#### Abstract

A data set of monthly growing areas of 26 irrigated crops (MGAG-I) and related crop calendars (CC-I) was compiled for 402 spatial entities. The selection of the crops consisted of all major food crops including regionally important ones (wheat, rice, maize, barley, rye, millet, sorghum, soybeans, sunflower, potatoes, cassava, sugar cane, sugar beets, oil palm, rapeseed/canola, groundnuts/peanuts, pulses, citrus, date palm, grapes/vine, cocoa, coffee), major water-consuming crops (cotton), and unspecified other crops (other perennial crops, other annual crops, managed grassland). The data set refers to the time period 1998-2002 and has a spatial resolution of 5 arc minutes by 5 arc minutes which is 8 km by 8 km at the equator.

This is the first time that a data set of cell-specific irrigated growing areas of irrigated crops with this spatial resolution was created. The data set is consistent to the irrigated area and water use statistics of the AQUASTAT programme of the Food and Agriculture Organization of the United Nations (FAO) (http://www.fao.org/ag/agl/aglw/aquastat/main/index.stm) and the Global Map of Irrigation Areas (GMIA) (http://www.fao.org/ag/agl/aglw/aquastat/irrigationmap/index.stm). At the cell-level it was tried to maximise consistency to the cropland extent and cropland harvested area from the Department of Geography and Earth System Science Program of the McGill University at Montreal, Quebec, Canada and the Center for Sustainability and the Global Environment (SAGE) of the University of Wisconsin at Madison, USA (http://www.geog.mcgill.ca/~nramankutty/ Datasets/Datasets.html and http://geomatics.geog.mcgill.ca/~navin/pub/Data/175crops2000/).

The consistency between the grid product and the input data was quantified. MGAG-I and CC-I are fully consistent to each other on entity level. For input data other than CC-I, the consistency of MGAG-I on cell level was calculated. The consistency of MGAG-I with respect to the area equipped for irrigation (AEI) of GMIA and to the cropland extent of SAGE was characterised by the sum of the cell-specific maximum difference between the MGAG-I monthly total irrigated area and the reference area when the latter was exceeded in the grid cell. The consistency of the harvested area contained in MGAG-I with respect to SAGE harvested area was characterised by the crop-specific sum of the cell-specific difference between MGAG-I harvested area and the SAGE harvested area when the latter was exceeded in the grid cell. In all three cases, the sums are the excess areas that should not have been distributed under the assumption that the input data were correct. Globally, this cell-level excess of MGAG-I as compared to AEI is 331,304 ha or only about $0.12 \%$ of the global AEI of 278.9 Mha found in the original grid. The respective cell-level excess of MGAG-I as compared to the SAGE cropland extent is 32.2 Mha , corresponding to about $2.2 \%$ of the total cropland area. The respective cell-level excess of MGAG-I as compared to the SAGE harvested area is $27 \%$ of the irrigated harvested area, or $11.5 \%$ of the AEI.

In a further step that will be published later also rainfed areas were compiled in order to form the Global data set of monthly irrigated and rainfed crop areas around the year 2000 (MIRCA2000). The data set can be used for global and continental-scale studies on food security and water use. In the future, it will be improved, e.g. with a better spatial resolution of crop calendars and an improved crop distribution algorithm. The MIRCA2000 data set, its full documentation together with future updates will be freely available through the following long-term internet site: http://www.geo.uni-frankfurt.de/ipg/ag/dl/forschung/MIRCA/index.html.

The research presented here was funded by the German Research Foundation (Deutsche Forschungsgemeinschaft, DFG) within the framework of the research project entitled "Consistent assessment of global green, blue and virtual water fluxes in the context of food production: regional stresses and worldwide teleconnections". The authors thank Navin Ramankutty and Chad Monfreda for making available the current SAGE datasets on cropland extent (Ramankutty et al., 2008) and harvested area (Monfreda et al., 2008) prior to their publication.

## Glossary

Term Definition

Annual crops
(temporary crops)

Area actually irrigated (AAI)

Area equipped for irrigation (AEI)

Area of irrigated crops
harvested (AIH)

Annual or temporary crops are those which are both sown and harvested during the same agricultural year, sometimes more than once. The agricultural year can start in one calendar year and end in the following year as e.g. for winter wheat.

Part of the full or partial control irrigated land which is actually irrigated in a given year. Often, part of the equipped area is not irrigated for various reasons, such as lack of water, absence of farmers, land degradation, damage, organisational problems etc. It refers only to physically used cadastral areas. Irrigated land that is cultivated more than once (e.g. twice) a year is counted once. Therefore always AEI $\geq$ AAI.

Area equipped to provide water to crops. It includes areas equipped for full control irrigation, equipped lowland areas, and areas equipped for spate irrigation. It does not include non-equipped cultivated wetlands and inland valley bottoms or non-equipped flood recession cropping areas. The area equipped for irrigation is larger than the area actually used for irrigation if parts of the existing infrastructure are not used (e.g. because of salinisation, water shortage, crop rotation etc.).

Annual harvested area of crops under irrigation. Irrigated land that is cultivated twice a year is counted twice. Therefore always AIH $\geq$ AAI. AEI that is barren or managed as rainfed land is not counted as AIH. Therefore AIH is smaller than the AEI when only a small fraction of the AEI is actually irrigated and the cropping intensity of irrigated crops is low. The AIH is larger than the AEI if a large part of the AEI is actually used for irrigation and if additionally the cropping intensity on irrigated land is high.

Area harvested of irrigated and rainfed crops
(SAGE harvested area)

Condensed Crop Calendar (for irrigated crops)
(CC-I)

Crop area Crop area is a surface of land on which a crop is grown (see also growing area).
The area harvested from the Center for Sustainability and the Global Environment (SAGE) excludes, like AIH, the area from which, although sown or planted, there was no harvest due to damage, failure, etc. In case of successive cultivation, i.e. when the same crop is sown or planted and cultivated more than once on the same field during the year, the area is counted as many times as harvested (twice, thrice, ...). From permanent crops the area harvested will be recorded only once. The SAGE harvested area includes irrigated and rainfed areas alike.

Crop calendar containing, for each crop class in a specific entity, cropping seasons with cultivation months and respective (irrigated) area, after the aggregation of crops of the detailed crop calendar belonging to the same crop class into a maximum of five sub-crops.
country code (e.g. 4 for Afghanistan) and in latter 3 digits the number of the specific sub-national entity. If only national level data exist, the last 3 digits are all zero. The formula is as follows: entity code $=$ UN*1000 + sub-national number.

Global Map of Irrigation
Areas
(GMIA)
Term

| Detailed crop calendar |
| :--- |
| (for irrigated crops) |

Cropland Arable land (including harvested cropland, crop failure, temporarily fallow or idle land, and cropland used temporarily for pasture) and land under permanent crops (such as cocoa, coffee, rubber, etc., including all tree crops except those grown for wood or timber).

Cropland extent Area of grid cell that is covered by cropland. Grid data are represented either as absolute area in hectare (ha) or as fraction or percentage of grid cell area.

Crop class Individual crop or group of crops (like e.g. pulses, citrus) that are treated as a single class. They possibly include a broad variety of crops, as for the last 3 classes in Tab. 2.1.

Cropping season Coherent period of 1 to 12 months during which a specific crop class or crop is cultivated continuously, defined by the month of begin (January for permanent crops), the month of end (month of harvest for temporary or annual crops, December for permanent crops). In case of the crop calendars for irrigated crops, the growing area of the crop is also specified.

Cropping intensity $\quad$ Ratio of annual sum of harvested area divided by the cultivated area. Given for a specific crop class or crop. In case of sub-crops with equal Given for a specific crop class or crop. In case of sub-crops with equal
growing area, the cropping intensity is equal to the number of cropping seasons.

Entity Spatial unit (country or sub-national unit) to which tabular and grid data is associated. Sub-national units are on the level of states (Australia, Brazil, India, and USA), provinces (Argentina, China) or geographically specified regions (Indonesia).

Unique number digits containing in the first 3 digits the United Nations

## Definition

The areas are valid for the whole spatial entity.
Crop calendar with monthly areas from January to December for each irrigated crop class. The areas are valid for the whole spatial entity. It shows cropping season(s) with currently used growing area, the start month and the end month of the period when the crop is cultivated, and the total harvested area, for any identified irrigated crop together with its assignment to a specific crop class. Thus, also multiple entries for the same class are contained if distinct areas per entity are found, e.g. lemons and oranges belonging to class "citrus".
crops, as for the last 3 classes in Tab. 2.1. -

Entity code

Area equipped for irrigation as grid area with 5 arc minutes resolution. Grid data are represented either as absolute area (in hectare) or as fraction or percentage of grid cell area.

| Term | Definition |
| :--- | :--- |
| Growing area | Actually cultivated area of a specific crop, i.e. the surface of land on <br> which a crop is actually grown. May be irrigated or not irrigated at a <br> specific point of time. For simplicity, for annual crops, the value refers <br> not to the sown area, but to the area at the time of harvest. |
| MGAG-I | Monthly Growing Area Grids, irrigated crops |
| MGAG-R | Monthly Growing Area Grids, rainfed crops |
| Maximum of monthly | It is the maximum monthly sum of the growing areas of irrigated <br> irrigated area <br> (MMIA) |
| AAI. Therefore always MMIA $\leq$ AEI and MMIA $\leq$ AIH and MMIA $\leq$ |  |
| Permanent crops | Permanent crops are sown or planted once and not replanted after each <br> annual harvest. |
| Shapefile | Sequence of lines and nodes (vertices) that delineate a spatial boundary <br> of at least 1 entity |
| Sub-crop | GIS file with polygons | | Distinct cropping season of the same crop class within the same spatial |
| :--- |
| entity. Sub-crops of detailed crop calendar represent cropping seasons |
| of crops as specified in the original data source (e.g. agricultural |
| census). Sub-crops of the Condensed Crop Calendar are the sum of |
| growing areas of irrigated crops listed in the detailed calendars, |
| belonging to the same crop class and growing during the same months |
| of the year. |

## 1. Introduction

For calculation of agricultural water use it is necessary to know where and when agricultural crops grow and when they are irrigated. This is especially important for global modelling that wants to depict the current and the possible future status of the global water resources. Up to now there is, to our knowledge, no spatially explicit, crop-specific global data set of growing areas of irrigated crops. A data set of growing areas with a 5 arc minute grid resolution and a distinction of rainfed and irrigated crops was compiled by (Heistermann, 2006), but presents only one dominant crop per grid cell, out of a list of 17 crops plus grazing land. Additionally, a global inventory showing the start and end of the cropping seasons of irrigated crops is still missing. The Food and Agriculture Organization of the United Nations (FAO) compiled such an inventory but it refers to the developing countries only (FAO, 2005a)

As the first part of the Global data set of monthly irrigated and rainfed crop areas around the year 2000 (MIRCA2000) currently in development we present here a consistent data set specifying crop calendars for 402 spatial entities and 26 irrigated crops and derived grids of monthly growing areas on a 5 arc minute by 5 arc minute grid resolution. The crop calendars were compiled mainly from national statistics, databases, and FAO reports. Sub-national information was used for China, India, USA, Brazil, Argentina, Indonesia, and Australia. Grids of monthly growing areas of irrigated crops were derived by combining the crop calendars with global data sets of the area equipped for irrigation from the Global Map of Irrigation Areas (Siebert et al., 2007), the cropland extent (Ramankutty et al., 2008) and the harvested area (Monfreda et al., 2008). The selected crops consist of all major food crops (wheat, rice, maize, barley, rye, millet, sorghum, soybeans, sunflower, potatoes, cassava, sugar cane, sugar beets, oil palm, rapeseed/canola, groundnuts/peanuts, pulses, citrus, date palm, grapes/vine, cocoa, coffee), major water-consuming crops (cotton), and unspecified other crops (other perennial crops, other annual crops, managed grassland). The data set refers to the time period 1998-2002. In the framework of this study crops are considered as irrigated if they are growing on areas equipped with irrigation infrastructure and receive irrigation water at least once during the cropping season. If, for example, in a specific country olives are irrigated during the flowering period in spring only, the related growing area is considered as irrigated for all months of the year. This is because olives are a permanent crop and received irrigation water at least once a year. The data set of monthly growing areas of irrigated crops should therefore not be interpreted in the way that in this country the olives receive irrigation water in all months of the year which is the related cropping season for permanent crops.

It is important to notice the exact meaning of the terminology used in this report (see the glossary). The input data and the methods used to generate the two elements of the part 1 of the data set, the Monthly Growing Area Grids of irrigated crops (MGAG-I) and the Condensed Crop Calendars of irrigated crops (CC-I) are presented in Chapter 2 of this report. In Chapter 3 the results are shown and discussed and a first assessment of the data set quality is performed for two examples. A summary and outlook is given in Chapter 4, followed by the bibliographic references. A practical example of the methodology for the distribution of growing area of the CC-I to the MGAG-I is given in Annex A. Area equipped for irrigation (AEI), area of irrigated crops harvested (AIH) and maximum of monthly irrigated area (MMIA) are listed by entity in Table B 1 in Annex B. References to the data sources used to develop the detailed crop calendars for irrigated crops are given in Annex C while the detailed crop calendars themselves are documented in Annex D. Finally, Annex E contains global maps of harvested area for the irrigated crops.

## 2. Data and methods

In this Chapter the input data (Chapter 2.1) and the methodology (Chapter 2.2) to compile the Monthly Growing Area Grids of irrigated crops (MGAG-I) and the Condensed Crop Calendars (CC-I) of the irrigated crops are described. Additional comprehensive information related to the methodology, the irrigated areas by entity, the data sources of the crop calendars and the crop calendars themselves are documented in Annexes A to D.

The selection of the 26 crop classes (Tab. 2.1) is based on the consideration of major food crops of the world used in previous studies (Leff et al., 2004). The 17 specific crops are complemented by permanent crops of regional importance (date palm, grapes, citrus, cocoa, and coffee), water-intensive cotton, and other 3 classes that contain all other types of crops to calculate a closed water balance (perennial, annual, managed grassland).

Tab. 2.1 Crop classes used in the MGAG-I

| Irrigated crop class | Irrigated crop class | Irrigated crop class |
| :---: | :---: | :---: |
| (1) Wheat | (10) Potatoes | (19) Date palm |
| (2) Maize | (11) Cassava | (20) Grapes/Vine |

| (8) Soybeans | (17) Pulses | (26) Others annual |
| (9) Sunflower | (18) Citrus |  |

### 2.1 Input data

Agricultural census statistics, databases, FAO reports, and other sources in various formats were used to develop crop calendars for 402 spatial entities. GIS-data in grid format (area equipped for irrigation, cropland extent, harvested area) and in polygon format (national and sub-national unit boundaries) were used to develop the MGAG-I (Tab. 2.2). In the following chapters, these data are described more in detail.

Tab. 2.2 Input data used to derive the MGAG-I

| No. of <br> data set | Data | Data type | Data source |
| :---: | :--- | :--- | :--- |
| 1 | Statistics on growing area <br> and cultivation periods of <br> irrigated crops | Tables and/or <br> reports for each <br> entity, absolute <br> areas, duration of <br> cultivation period | National agricultural census <br> statistics, national reports, <br> databases, FAO, USDA <br> (see Annex C) |
| 2 | Area equipped for irrigation | 5 arc min grid, <br> fractions of grid <br> cell area | Global Map of Irrigation <br> Areas (GMIA), version 4 <br> (Siebert et al., 2007) |
| 3 | Cropland extent <br> (area or fraction of each grid <br> cell covered by cropland) | 5 arc min grid, <br> fractions of grid <br> cell area | SAGE cropland extent <br> (Ramankutty et al., 2008) |
| 4 | Crop-specific annual <br> harvested area <br> (total area, 26 classes) | 5 arc min grid, <br> fractions of grid <br> cell area, total | SAGE harvested area <br> (Monfreda et al., 2008) |
| 5 | Administrative boundaries <br> of countries and sub-national <br> units | GIS-Shapefile | (ESRI, 2004) |

### 2.1.1 Agricultural statistics to develop detailed crop calendars for irrigated crops

To compile tabular crop calendars that give, for each spatial entity, the monthly growing area of each irrigated crop group, a compilation of data on the crop-specific growing area of irrigated crops and the begin and end of the related cultivation period was needed. The detailed listing of the data sources is available in Annex C. In the following the sources are briefly described.

## Growing area

To define for irrigated crops their specific annual harvested area or growing area of individual cultivation periods, for most of the developing countries the validated data provided by the FAO AQUASTAT reports ((FAO, 1999), (FAO, 1995), (FAO, 1997b), (FAO, 1997a), (FAO, 2000), (FAO, 2005c)) were used and complemented by information derived from the FAO crop calendars for irrigated crops (FAO, 2005a). For the developed countries national statistical services were used as often as possible. For European developed countries data from (EUROSTAT, 2005) was used as major information source. Reports of development agencies, e.g. (Dirksen and Huppert, 2006), and World Bank reports on agricultural sector, e.g. (World Bank, 2001), were used for eastern European countries.

## Cultivation period

FAO crop calendars for irrigated crops that are available for a number of developing countries (FAO, 2005a) were used as a starting point to define cultivation periods for the specific entities. The
cropping seasons were validated and complemented with data from other sources reporting months of cultivation without a distinction of irrigated and non-irrigated crops, e.g. (FAO, 2005b), (USDA, 1994), (IRRI, 2005). For countries without any data, the cropping seasons of crop calendars of neighbouring countries were consulted and extended. In case of the sub-national entities, either already existing FAO calendars for sub-national climatic or cultivation zones ( 3 for China, 4 for India, 2 for Indonesia) were adapted or new calendars were established according to climatic zones and climatic classifications based on station data or reports (6 for Argentina, 8 for Australia, 5 for Brazil, 8 for USA).

### 2.1.2 Areas equipped for irrigation

The Global Map of Irrigation Areas (GMIA) in its latest version 4.0.1 (Siebert et al., 2007) was used to define the area equipped for irrigation for each 5 arc minute by 5 arc minute cell. The area is given as hectare per grid cell, or as fraction or percentage of grid cell area. The GMIA was developed by combining sub-national irrigation statistics with geo-spatial information on the location and extent of irrigation schemes. For most of the countries the statistics used to develop the GMIA are consistent to statistics used elsewhere in this report (e.g. to define the crop calendars).

### 2.1.3 Cropland extent

The extent of cropland in each 5 arc minute by 5 arc minute cell was derived from the global data set of the Department of Geography and Earth System Science Program of the McGill University at Montreal, Quebec, Canada and the Center for Sustainability and the Global Environment (SAGE) of the University of Wisconsin at Madison, United States of America (Ramankutty et al., 2008) as downloaded on 2008-02-18 from http://www.geog.mcgill.ca/~nramankutty/Datasets/Datasets.html. The data set is hereafter referred to as the SAGE cropland extent. It was developed by combining statistics on cropland extent with land cover from satellite-based remote sensing information of 1 km spatial resolution. Cropland is all arable land (including harvested cropland, crop failure, temporarily fallow or idle land, and cropland used temporarily for pasture) and land under permanent crops such as citrus, cocoa, coffee, etc., including all tree crops except those grown for wood or timber ((Ramankutty, 2004), (Ramankutty and Foley, 1998)).

### 2.1.4 Harvested areas

Total harvested area (sum of irrigated and rainfed) for each of the 26 crops or crop groups and each 5 arc minute by 5 arc minute cell was derived from the global data set of SAGE (Monfreda et al., 2008) as downloaded on 2008-02-07 from http://geomatics.geog.mcgill.ca/~navin/pub/Data/ 175 crops $2000 /$. The data set is hereafter referred to as the SAGE harvested area. It was developed by scaling available sub-national statistics of reporting administrative spatial entities to nationallevel statistics of the Food and Agricultural Organization of the United Nations (FAO) and disaggregating entity-level totals to the grid cells with the help of the SAGE cropland extent. The harvested area is the area on which a specific product is harvested at the end of the specific cropping season. When several cropping seasons exist for a given crop class, then the total annual harvested area is the sum of the individual growing areas. The 175 primary crop classes of the SAGE harvested area data set correspond to the crop classification of the FAO. To get the correct areas for the crop classes in Tab. 2.1, for some crop classes the harvested area of more than one primary crop class was summed: maize ( 3 FAO crop classes), rye (2), sorghum (2), pulses (11, grouping of FAO), citrus (5, grouping of FAO), other perennial crops (57), managed grassland (5) and other annual crops (72). The area of the FAO class "Forage Products, other" was distributed equally to the last two classes of managed grassland and other annual crops.

### 2.1.5 Administrative boundaries

Country frontiers and sub-national administrative boundaries for the reference year 2004 (ESRI, 2004) were used as a basis to assign the grid cells to spatial entities. For a number of entities, the setting of the sub-national statistical units was different from that one provided by the ESRI-data set. In those cases a shapefile of sub-national unit boundaries compiled to develop the Global Map of Irrigation Areas (Siebert et al., 2007) was used. In total 402 spatial entities were considered here (Fig. 2.1) and for each of these entities crop calendars for irrigated crops were defined.

Fig. 2.1 Administrative boundaries of countries and sub-national units used in the data set

### 2.2 Methodology

In the following chapters we describe the methodology used to develop the monthly cell-specific growing area grids of irrigated crops and the related crop calendars. The compilation of detailed crop calendars for the specific entities is described in Chapter 2.2.1. In Chapter 2.2.2 we describe how the Condensed Crop Calendars for irrigated crops were derived from the detailed crop calendars. The development of the entity mask is documented in Chapter 2.2.3, while the procedure to assign crop-specific monthly growing area to specific grid cells is explained in Chapter 2.2.4.

### 2.2.1 Compilation of detailed crop calendars for irrigated crops

Detailed crop calendars, as documented in Annex D for the 352 entities with irrigation, list for each specific spatial entity (Fig. 2.1) the crop-specific monthly growing area of irrigated crops. In general, the crop classification used in the detailed crop calendars is the same as used in the original data source and differs therefore from entity to entity (Annex C). However, often primary data sources group specific crops into crop classes that are not identical to the crop classes used in this inventory. Additionally in many cases only harvested areas of the major irrigated crops were reported. EUROSTAT for example reports for many European countries the growing area irrigated at least once a year, as a total over all crops and for the crops or crop groups durum wheat, maize, potatoes, sugar beet, sunflower, soybean, fodder plants, fruit and berry orchards, citrus and vines (EUROSTAT, 2007). The sum of the reported crop-specific irrigated areas was often much lower
than the reported total irrigated area because some important irrigated crops were missing in the EUROSTAT list of irrigated crops (e.g. rice, cotton, vegetables). Therefore, based on information that was derived from other data sources and that is documented in Annex C, these crop calendars had to be complemented by irrigated crops which were missing in the original list. For crop groups mentioned in the original data source but not used in this inventory (e.g. fodder crops) assumptions based on the available literature and additional statistical data e.g. from FAOSTAT were used to disaggregated the values.

### 2.2.2 Derivation of Condensed Crop Calendars for irrigated crops

Condensed crop calendars list for each entity the crop-specific monthly growing area for each of the irrigated classes used in this inventory (Tab. 2.1). To define the Condensed Crop Calendars for irrigated crops, each crop entry in the detailed crop calendars was assigned to the related crop class used in this inventory (see first column in the detailed crop calendars in Annex D). Then the sum of growing areas of irrigated crops listed in the detailed calendars, belonging to the same crop class and growing during the same months of the year, was calculated. By doing so, up to five so called sub-crops were defined in the condensed calendars. Thus, sub-crops can represent multi-cropping systems, e.g. double cropping or triple cropping of rice in southern Asia. They can also represent different specific sub-groups of a crop class that grow during different parts of the year, also with overlapping cropping seasons.

### 2.2.3 Development of the entity mask used to assign grid cells to entities

To combine information collected at the entity level (Condensed Crop Calendars for irrigated crops) with information available at the grid cell level (AEI, cropland extent, harvested area) it was necessary to assign each grid cell to the related entity (country or sub-national unit). Usually, this is done by converting a polygon shapefile containing entity boundaries to a raster data set of the required resolution. As irrigated cropland is often located in lowland cells close to the coastline and as different land masks were used to generate the grids used as input data, it occurs frequently that grid cells close to the sea contain data in one input data set but are masked out as ocean in the polygon shapefile (ESRI, 2004) to be used here. In order to avoid that a significant fraction of the input areas are masked out, a procedure was developed to assign the ocean cells in the entity grid to the entity that is closest to the related grid cell (Fig. 2.2). This procedure was performed using the ArcGIS 9.0 software (ESRI, Redlands, California, US) and consisted of four steps. First, a polygon shapefile containing all desired spatial entities was compiled (Fig. 2.1). Each spatial entity got as attribute a unique 6 -digit entity code composed of the United Nations country code (1st 3 digits) and the code of the sub-national unit, starting with 1, e.g. 840001 for Alabama in the United States of America (Tab. B 1). Then the polygon shapefile was converted to a grid of a 30 arc second by 30 arc second resolution containing the entity codes and No Data values for ocean cells. In the third step the entity code of the closest entity was assigned to ocean cells using the Euclidean distance allocation tool. Finally, the grid was aggregated to a 5 arc minute by 5 arc minute resolution.

Fig. 2.2 Generation of a mask with entity codes used to assign entities to grid cells

### 2.2.4 Derivation of crop-specific monthly growing area of irrigated crops for each grid cell

The derivation of crop-specific monthly growing area of irrigated crops for each grid cell requires the combination of the Condensed Crop Calendar defined for each entity with grid data on AEI, cropland extent and total (irrigated and rainfed) harvested area of each crop. If these four input data sets were fully consistent to each other, a data set with the characteristics described in Tab. 2.3 would result.

However, because of the different data sources and methods used to develop the four input data sets it is obvious that there must be inconsistencies between the input data, at least at the grid cell level. To illustrate this, the AEI grid from the GMIA was compared to the cropland extent grid for the country of Egypt (Fig. 2.3). Fig. 2.3a shows for each cell the minimum of AEI and cropland extent as percentage of the total cell area and represents thus the areas where we would expect to find irrigated crops. The corresponding total area is 2.3 Mha . Fig. 2.3b shows the area where the cropland extent is larger than the AEI and represents thus rainfed cropping areas, with a sum of only about 56,000 ha. Fig. 2.3 c shows the area where AEI is larger than cropland extent and represents thus areas of unused irrigation infrastructure, in total 1.1 Mha . According to the FAO statistics about 3.4 Mha of agricultural land are equipped for irrigation in Egypt and the whole area is actually being used. The annual harvested area of irrigated crops is about 6 Mha which corresponds to a cropping intensity of $176 \%$ on irrigated land (FAO, 2005c). If, as reported, all the areas equipped for irrigation were actually used for irrigation, the cropland extent should be everywhere in Egypt equal to or larger than the AEI. However, this is not the case. The areas shown in Fig. 2.3c represent therefore inconsistencies between the SAGE cropland extent set and the GMIA.

[Percent of cell area]

5-10
10-30
$30-70$
$>70$
$>70$
(b)
$\qquad$

Fig. 2.3 Comparison between area equipped for irrigation (Siebert et al., 2007) and cropland extent (Ramankutty et al., 2008), both shown as percentage of total grid cell area, for the country of Egypt:
(a) Minimum of AEI and cropland extent
(b) Cropland minus AEI in grid cells where cropland extent was higher than AEI
(c) AEI minus cropland in grid cells where AEI was higher than cropland extent.

The consequence of this finding is that it is impossible to generate grids of crop-specific monthly growing area of irrigated crops that are fully consistent to all of the four input data sets used here. Instead of it, a methodology was developed so that the consistency of the resulting data product to the four input data sets is in agreement to predefined levels of priority, either fully or as much as possible (Tab. 2.3). The methodology used to achieve this (Fig. 2.4) consists of six steps and is described in the following sections. The consistency levels have the following meaning: First, the monthly sum of crop-specific irrigated areas in all grid cells belonging to an entity is always equal to the crop-specific monthly growing area defined in the Condensed Crop Calendar of a specific entity. Furthermore, in each month and grid cell the sum of crop-specific irrigated areas is lower than or equal to the AEI. This is met in most of the entities (see step 1). Also, in each grid cell and month the sum of crop-specific irrigated areas is lower than or equal to the SAGE cropland
extent. This could not always be respected (see step 4). Finally, in each grid cell and for each crop class the annual sum of the irrigated harvested area would be lower or equal to the total (rainfed and irrigated) SAGE harvested area. This principle was applied as much as possible (see steps 2 and 3).

The methodology used to achieve this (Fig. 2.4) is presented in the following sections and consists of six steps. A practical example to illustrate the calculation principle is presented in Annex A.

Tab. 2.3 Priority levels of consistency of the data set of Monthly Growing Area Grids of irrigated crops (MGAG-I) to information used as input data

| Consis- Related input data set | Interpretation |
| :--- | :--- |
| tency |  |
| priority |  |

1 Condensed Crop Calendars The monthly sum of crop-specific irrigated areas in all grid cells belonging to an entity is equal to the cropspecific monthly growing area defined for the entity in the Condensed Crop Calendars for irrigated crops.

2 Area equipped for irrigation of In each month and grid cell the sum of crop-specific Global Map of irrigation irrigated areas is lower than or equal to the AEI.
Areas
3 SAGE cropland extent
In each grid cell and month the sum of crop-specific irrigated areas is lower than or equal to the SAGE cropland extent.

4 SAGE harvested area
In each grid cell and for each crop class the annual sum of the irrigated harvested area would be lower or equal to the total (rainfed and irrigated) SAGE harvested area of the specific crop.

Fig. 2.4 Data processing scheme for the derivation of Monthly Growing Area Grids of irrigated crops

## Step 1

First it was necessary to increase the AEI of GMIA for 30 entities in 18 countries by using 1 (or exceptionally 2) coefficients kept constant for all considered grid cells of the same entity. First, the AEI of all cells that contained cropland were scaled with a first coefficient. In one case AEI was still lower than the reference statistics and therefore also the AEI in cells without cropland was scaled. The reason for the deviations was that the base years of the statistics used to generate the GMIA and the base years of the reference statistics used to generate the Condensed Crop Calendars for irrigated crops were different for several countries. In addition to this, the statistics for the countries of Australia and India used to develop the Global Map of Irrigation Areas refer to the area actually irrigated because the AEI was not available for these countries (Siebert et al., 2007). Applying this scaling procedure, it was ensured that all monthly growing areas of the Condensed Crop Calendars could be distributed within the grid cells of the related entities without surpassing the AEI in any month. Thus, the AEI grid was made consistent to the Condensed Crop Calendars for irrigated crops (Tab. 2.3).

In the following steps, the crop-specific monthly growing area of irrigated crops in the Condensed Crop Calendars was distributed to specific grid cells. For each crop and sub-crop and in each entity with irrigation ( 352 out of 402 entities), the sum of the growing areas distributed during the different steps was equal to the growing area for the specific entity reported in the Condensed Crop Calendars for irrigated crops (Tab. 2.3, Eq. 1).
$A G i=A G i \_$base $+A G i 3+A G i 4+A G i 5+A G i 6$
where AGi was the irrigated growing area of the sub-crop (or season) as reported in the Condensed Crop Calendar (in ha), AGi_base was the irrigated growing area distributed in step 2 (in ha), AGi3 was the irrigated growing area distributed in step 3 (in ha), AGi4 was the irrigated growing area distributed in step 4 (in ha), AGi5 was the irrigated growing area distributed in step 5 (in ha) and AGi6 was the irrigated growing area distributed in step 6 (in ha).

## Step 2

In each grid cell and for each irrigated crop and sub-crop growing in the related entity a so called base growing area was distributed, valid for each month of the related cropping seasons. The base growing area was computed as:

AGi_base(cell,crop $)=\frac{\text { AH(cell,crop) }}{\text { number_of_subcrops }{ }_{i}(\text { crop })} * \frac{A E I(C e l l)}{\text { cell_area(cell) }}$
where $A H$ (cell,crop) was the cell-specific total (irrigated and rainfed) harvested area of the crop class in ha $\mathrm{yr}^{-1}$, AEI(cell) was the cell-specific area equipped for irrigation in ha, cell_area(cell) was the total cell area in ha and number_of_subcrops $s_{i}($ crop $)$ was the number of sub-crops (cropping seasons) reported in the Condensed Crop Calendar for the related entity and irrigated crop. If, this way, for a crop the entity sum of the base growing area was larger than the minimum of the sub-crop growing areas, the base growing area was scaled down to this minimum area. One example: rice was growing in an entity in two sub-crops. Sub-crop 1 was growing on 1,000 ha from March to June and sub-crop 2 was growing on 400 ha from July to October. The first preliminary calculation of sum of the cellspecific base growing areas for rice was 800 ha . Then the base growing area computed for each grid cell was multiplied by 0.5 (i.e. $400 / 800$ ) so that the sum of the base growing areas for rice in the whole entity equals 400 . The base growing area computed this way was distributed to all months in the period from March to October. By performing step 2, a significant fraction of the monthly growing area of each irrigated crop class was distributed to the grid cells and the data product was still completely consistent to the SAGE cropland extent and to the SAGE harvested area.

## Step 3

Beginning with step 3, the distribution of irrigated growing area to grid cells was performed crop by crop and sub-crop by sub-crop. It used three levels of sorting criteria to decide which crop or subcrop had to be processed first:

1. Specific perennial crops (sugar cane, oil palm, citrus, date palm, grapes/vine, cocoa, coffee) were processed first, followed by the group of perennial other crops (others perennial and managed grassland) and then by specific annual crops (wheat, maize, rice, barley, rye, millet, sorghum, soybeans, sunflower, potatoes, cassava, sugar beets, rapeseed/canola, groundnuts/peanuts, pulses). Finally the group of "others annual" was processed.
2. The decision which of the specific crops had to be processed first within the aforementioned groups of crops was based on the amount of the annual irrigated harvested area of the crop; the crop with the largest harvested crop area was processed first.
3. If a crop class had several sub-crops, the sub-crop with the largest irrigated harvested subcrop area was processed first.

It is obvious that the ranking of crops and sub-crops used for these steps strongly affected the cell-specific spatial pattern of monthly growing areas of irrigated crops. This was because
monthly growing area occupied by one crop was no more available for crops processed later and growing in the same month.

Step 3 was performed for crops and sub-crops with the sequence of priorities described above only if the related crop growing area per entity and sub-crop was not already completely distributed at the end of step 2. By performing step 3 irrigated growing area was distributed to grid cells using the minimum of free harvested crop area and free seasonal AEI.

## Step 3.1

First the free AEI and the free harvested area was computed for each cell of the entity as:
AEI_free(cell) $=A E I($ cell $)-\max \left(\sum_{\text {crops }} A G i_{-}\right.$distributed $_{m_{-} s}, \ldots, \sum_{\text {crops }} A G i_{-}$distributed $\left._{m_{-} e}\right)$
and
AH_free(cell,subcrop) $=\left(\begin{array}{ccc}\text { ci } i_{i}^{*} \text { AH(cell,crop) }- \text { AGi_base(cell,crop) } & \text { if } & c_{i}{ }^{*} A H \text { (cell,crop) }> \\ 0 & \text { else }\end{array}\right.$
with
$c i_{i}=\frac{1}{\text { number_of_subcrops }{ }_{i}(\text { crop })}$
where $A E I$ _free(cell) was the cell-specific area equipped for irrigation still available during the subcrop cropping season in ha, $A E I(c e l l)$ was the total area equipped for irrigation in the grid cell (in ha), $\sum_{\text {crops }} A G i_{-}$distributed $_{m_{-} s}$ was the total growing area that was already distributed before to all crops growing in the first month of the cropping season of the processed sub-crop in ha, $\sum_{\text {crops }} A G i_{-}$distributed $_{m_{-} e}$ was the total growing area that was already distributed before to crops growing in the last month of the cropping season of the processed sub-crop in ha, AH_free(cell,subcrop) was the cell-specific free harvested area that could thus still be distributed to the sub-crop in ha $\mathrm{yr}^{-1}, c i_{i}$ was a scaling coefficient considering the cropping intensity of the irrigated crops through the division by number_of_subcrops ${ }_{i}$ (crop), the number of sub-crops (cropping seasons) reported in the Condensed Crop Calendar for the related entity and irrigated crop, and AGi_base(cell,crop) was the total harvested area already distributed to the crop in the specific grid cell in ha. The procedure of computing AEI_free(cell) ensured for all grid cells that the total monthly growing area of all irrigated crops never exceeded the area equipped for irrigation. The procedure of computing AH_free(cell,subcrop) ensured for each grid cell that the harvested area of the specific irrigated crop never exceeded the maximum possible total (irrigated and rainfed) SAGE harvested area for this crop.

## Step 3.2

Now, for the whole entity, the growing area that still had to be distributed to the sub-crop (Eq. 3.4) and the growing area that potentially could be distributed in this step (Eq. 3.5) was computed as following:

AGi3_to_distribute(entity,subcrop) $=$ AGi(entity,subcrop) - AGi_distributed(entity, subcrop)
and
AGi3_pot(entity,subcrop) $=\sum_{\text {cells }} A G i 3_{-}$pot(cell, subcrop)
with
AGi3_pot(cell,subcrop $)=\min \left(A E I \_\right.$free(cell), AH_free(cell,subcrop) $)$
where AGi3_to_distribute(entity,subcrop) was the growing area that still needed to be distributed to the sub-crop (in ha), AGi(entity,subcrop) was the total growing area of the sub-crop in the processed entity as derived from the Condensed Crop Calendar for irrigated crops (in ha), AGi_distributed(entity,subcrop) was the growing area already distributed to the sub-crop in steps performed before (in ha), AGi3_pot(entity,subcrop) was the total growing area that potentially could be distributed in step 3 to the sub-crop within the whole entity (in ha) and AGi3_pot(cell,subcrop) was the total growing area that potentially could be distributed in step 3 to the sub-crop within a specific grid cell (in ha).

## Step 3.3

The potential growing area computed in Equation (3.6) was distributed to the sub-crop in each grid cell if the entity sum computed in Equation (3.5) was not larger than the growing area that still had to be distributed as computed in Equation (3.4), otherwise AGi3_pot(cell,subcrop) was scaled down using the scaling coefficient $\uparrow 3$. This procedure, described in Equations (3.7) and (3.8), ensured that in step 3 the total growing area distributed to the sub-crop was not becoming larger than the growing area of the sub-crop reported in the Condensed Crop Calendar for irrigated crops.

AGi3(cell,subcrop) $=f 3($ entity, subcrop $) *$ AGi3_pot(cell,subcrop)
with
$f 3($ entity, subcrop $)=\left\{\begin{array}{ccc}\frac{\text { AGi3_to_distribute(entity, subcrop) }}{\text { AGi3_pot(entity,subcrop) }} & \text { if } \begin{array}{l}\text { AGi3_to_distribute(entity,subcrop) } \\ 1\end{array} & \text { else }\end{array}\right.$
where AGi3(cell,subcrop) was the cell-specific growing area distributed to the sub-crop by performing step 3 (in ha) and $f 3$ (entity,subcrop) was the dimensionless scaling coefficient used in the entity in step 3.

## Step 4

Step 4 was performed only if the related sub-crop irrigated growing area per entity was not already completely distributed at the end of step 3 . By performing step 4, irrigated growing area was distributed to grid cells containing cropland (without being a quantitative limitation), free seasonal AEI, but no free harvested area for the crop class containing the sub-crop to be processed. Therefore, the irrigated growing areas distributed in step 4 generated in many cases an inconsistency of the MGAG-I data product to the SAGE cropland extent and to SAGE harvested areas used as input data.

## Step 4.1

First the free cell-specific AEI was computed as:
$A E I_{-}$free(cell) $=\left\{\begin{array}{ccc}\operatorname{AEI}(\text { cell })-\max \left(\sum_{\text {crops }} A G i_{-} \text {distributed }_{m_{-} s}, \ldots, \sum_{\text {crops }} A G i_{-} \text {distributed }_{m_{-} e}\right) & \text { if } \begin{array}{c}\left.A H_{-} \text {free(cell, subcrop }\right)=0 \\ 0 \\ \text { and } A C L(c e l l)>0\end{array} \\ \text { else }\end{array}\right.$
where $A C L$ (cell) was the total cropland located in the grid cell and AH_free(cell subcrop) was the cellspecific free harvested area of step 3 that could still be distributed to the sub-crop (in ha $\mathrm{yr}^{-1}$ ).

## Step 4.2

Now, similar to step 3.2, the growing area that still had to be distributed to the sub-crop and the growing area that potentially could be distributed was computed for the whole entity as:

AGi4_to_distribute(entity,subcrop) $=$ AGi(entity,subcrop) - AGi_distributed(entity, subcrop)
and
AGi4_pot(entity,subcrop) $=\sum_{\text {cells }} A G i 4 \_$pot(cell, subcrop $)$
with
AGi4_pot(cell, subcrop) $=A E I_{\_}$free (cell)
where AGi4_to_assign(entity,subcrop) was the growing area that still needed to be distributed to the subcrop (in ha), AGi4_pot(entity,subcrop) was the total growing area that potentially could be distributed in step 4 to the sub-crop within the whole entity (in ha) and AGi4_pot(cell,subcrop) was equal to the free area equipped for irrigation (in ha).

## Step 4.3

Similar to step 3.3, growing area was distributed to specific grid cells. The scaling coefficient $f 4$ was used to ensure that the total growing area distributed to the sub-crop in the whole entity was not becoming larger than the growing area reported in the Condensed Crop Calendar for irrigated crops.

$$
\begin{equation*}
\text { AGi4 }(\text { cell, subcrop })=f 4(\text { entity }, \text { subcrop }) * \text { AGi4_pot(cell, subcrop }) \tag{4.5}
\end{equation*}
$$

with

$$
f 4(\text { entity }, \text { subcrop })=\left\{\begin{array}{ccc}
\frac{\text { AGi4_to_distribute(entity, subcrop) }}{\text { AGi4_pot(entity,_subcrop) }} & \text { if } & \begin{array}{c}
\text { AGi4_to_distribute(entity,subcrop) }) \\
1
\end{array}  \tag{4.6}\\
\text { else }
\end{array}\right.
$$

where AGi4(cell,subcrop) was the cell-specific growing area distributed to the sub-crop by performing step 4 (in ha) and f4(entity,subcrop) was the dimensionless scaling coefficient used in the entity in step 4.

## Step 5

Step 5 was performed only if the related sub-crop irrigated growing area per entity was not already completely distributed at the end of step 4 . By performing step 5 irrigated growing area was distributed to grid cells in which AEI was located but no cropland (and by consequence no SAGE harvested area) did exist. Therefore, irrigated growing areas distributed in step 5, generated an inconsistency of the MGAG-I data product to the SAGE cropland extent (Ramankutty et al., 2008) and to the SAGE harvested area (Monfreda et al., 2008).

## Step 5.1

The free AEI was computed for each grid cell as:
$A E I_{-}$free (cell) $=\left\{\begin{array}{cc}\operatorname{AEI}(\text { cell })-\max \left(\sum_{\text {crops }} A G i_{-} \text {assigned }_{m_{-} s}, \ldots, \sum_{\text {crops }} A G i_{-} \text {assigned }_{m_{-} e}\right) & \text { if } A C L(\text { cell })=0 \\ 0 & \text { else }\end{array}\right.$

## Step 5.2:

Now, similar to step 3.2, the growing area that still had to be distributed to the sub-crop and the growing area that potentially could be distributed was computed for the whole entity as:

AGi5_to_distribute(entity,subcrop) $=$ AGi(entity,subcrop) - AGi_distributed(entity, subcrop)
and
AGi5_pot(entity,subcrop) $=\sum_{\text {cells }} A E I_{-}$free(cell)
where AGi5_to_assign(entity,subcrop) was the growing area that still needed to be distributed to the subcrop (in ha) and AGi5_pot(entity,subcrop) was the total growing area that potentially could be distributed in step 5 to the sub-crop within the whole entity (in ha).

## Step 5.3

Similar to step 3.3 growing area was distributed to specific grid cells. The scaling coefficient $f 5$ was used to ensure, that the total growing area distributed to the sub-crop in the whole entity was not becoming larger than the growing area reported in the Condensed Crop Calendar for irrigated crops.

AGi5(cell, subcrop) $=f 5($ entity, subcrop $) * A E I \_$free(cell)
with
$f 5($ entity, subcrop $)=\left\{\begin{array}{ccc}\frac{\text { AGi5_to_assign(entity, subcrop) })}{\text { AGi5_pot(entity, subcrop) }} & \text { if } & \begin{array}{l}\text { AGi5_to_assign(entity,subcrop) }) \\ 1\end{array} \\ \text { eAGi5_pot(entity, subcrop) }\end{array}\right.$
where AGi5(cell,subcrop) was the cell-specific growing area distributed to the sub-crop by performing step 5 (in ha) and $f 5$ (entity,subcrop) was the dimensionless scaling coefficient used in the entity in step 5.

## Step 6

Step 6 was performed only if the related sub-crop irrigated growing area per entity was not already completely distributed at the end of step 5 . By performing step 6 irrigated growing area was distributed to grid cells having free seasonal AEI, cropland and harvested area for the crop class containing the sub-crop to be processed. At this stage, all the harvested area for the crop class from the SAGE harvested area was already distributed. Now, additionally needed area was distributed where free AEI was available in addition to SAGE harvested area distributed in steps 2 and 3. It intensified the irrigated growing areas at theses grid cells, while in the steps 4 and 5, that were executed before, additionally needed harvested area was already distributed to grid cells that did not contain free harvested area of the currently processed crop class (in step 4) or did not contain any cropland (in step 5). Therefore, the required additional harvested area was generated in cells that still contained any free seasonal AEI. Because of the limitations applied in step 3, this free seasonal AEI was available in cells containing some harvested area of the crop class currently processed,. Irrigated growing areas distributed in step 6 generated an inconsistency of the MGAG-I data product to the SAGE harvested area (Monfreda et al., 2008) and in many cases also to the SAGE cropland extent (Ramankutty et al., 2008).

## Step 6.1

The free cell-specific AEI was computed as described in Equation (3.1).

## Step 6.2

Now, similar to step 3.2, the growing area that still had to be distributed to the sub-crop and the growing area that potentially could be distributed was computed for the whole entity as:

$$
\begin{equation*}
\text { AGi6_to_distribute(entity,subcrop) }=\text { AGi(entity,subcrop) }- \text { AGi_distributed (entity, subcrop) } \tag{6.1}
\end{equation*}
$$

and
AGi6_pot(entity,subcrop) $=\sum_{\text {cells }} A E I_{-}$free(cell)
where AGi6_to_assign(entity,subcrop) was the growing area that still needed to be distributed to the subcrop (in ha) and AGi6_pot(entity,subcrop) was the total growing area that potentially could be distributed in step 6 to the sub-crop within the whole entity (in ha).

## Step 6.3

Similar to step 3.3 growing area was distributed to specific grid cells. The scaling coefficient $f 6$ was used to ensure, that the total growing area distributed to the sub-crop in the whole entity was not becoming larger than the growing area reported in the Condensed Crop Calendar for irrigated crops.

AGi6(cell, subcrop) $=f 6($ entity, subcrop $) * A E I \_$free(cell)
with
$f 6($ entity, subcrop $)=\left\{\begin{array}{ccl}\frac{\text { AGi6_to_distribute(entity, subcrop) }}{\text { AGi6_pot(entity, subcrop) }} & \text { if } & \begin{array}{l}\text { AGi6_to_distribute(entity, subcrop) } \\ \text { < AGi6_pot(entity, subcrop) }\end{array} \\ 1 & \text { else }\end{array}\right.$
where AGi6(cell,subcrop) was the cell-specific growing area distributed to the sub-crop by performing step 6 (in ha) and f6(entity,subcrop) was the dimensionless scaling coefficient used in the entity in step 6.

At the end of step 6 all the required irrigated growing area was distributed to specific grid cells and to the specific months within the cropping season of the currently treated sub-crop.

## 3. Results and discussion

In this Chapter, the following issues are discussed: the form of the Condensed Crop Calendars for irrigated crops (Chapter 3.1), the global values of harvested area for all irrigated crop classes (Chapter 3.2), the annual cycle of the global monthly growing areas of irrigated wheat, rice, maize, and cotton (Chapter 3.3) and global maps of monthly growing areas of these selected major irrigated crops in January and July (Chapter 3.4). Furthermore, a map shows the total irrigated harvested area for the whole world (Chapter 3.5). Finally, the results are validated and discussed in Chapter 3.6, comparing the results of the methodology with the results of a simpler distribution algorithm (Chapter 3.6.1), showing the improvement through the usage of sub-national data (Chapter 3.6.2), and comparing the data set with independent data for Egypt (Chapter 3.6.3) and for Europe (Chapter 3.6.4).

### 3.1 Crop calendars for irrigated crops

Detailed crop calendars for irrigated crops were compiled for all of the 402 spatial entities where irrigation was practised, with growing area of individual crops (see Chapter 2.2.1 and Annex D). In the derived Condensed Crop Calendars of irrigated crops (CC-I) the cropping seasons with growing areas and months of cultivation for up to five sub-crops per crop class are given. This information can be used separately from the MGAG-I.

A hypothetic example of CC-I of a hypothetic entity is shown in Tab. 3.1: Rice is double cropped with two cropping seasons following each other (March - June and July - October) and different sub-crop growing areas ( 500 and $1,000 \mathrm{ha}$ ), which results in $500+1000=1,500$ ha annually harvested area. The maize crop class may contain maize for forage and maize for grain that are cultivated on 1,500 ha during the same cropping season (June - October). Sorghum is cultivated during the same months of the year as maize on 500 ha. Perennial crops without specification are cultivated throughout the year at a constant growing area of $2,000 \mathrm{ha}$. Other annual crops are cultivated in one cropping season from June to October with 1,000 ha growing area. For simplicity purposes, crops that have no harvested area are not represented in the table.

Tab. 3.1 Hypothetic Condensed Crop Calendar for irrigated crops, for a specific entity, only crop classes with harvested area

| Crop name | Crop <br> class | Sub-crop <br> no. | Sub-crop <br> growing area <br> [ha] | Month Begin | Month End |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Maize | 2 | 1 | 1,000 | 6 | 10 |
| Rice | 3 | 1 | 500 | 3 | 6 |
| Rice | 3 | 2 | 1,000 | 7 | 10 |
| Sorghum | 7 | 1 | 500 | 6 | 10 |
| Others perennial | 24 | 1 | 2,000 | 1 | 12 |
| Others annual | 26 | 1 | 1,000 | 6 | 10 |

### 3.2 Global harvested area of irrigated crops

Globally, the irrigated crops with the largest harvested area are rice (103.1 Mha), wheat ( 66.7 Mha ), maize (29.9 Mha), cotton (16.2 Mha), managed grassland (11.7 Mha) and sugar cane (10.2 Mha) (Tab. 3.2). The harvested area of other annual crops was 20.1 Mha , followed by other perennial crops ( 12.8 Mha ). Coffee has a relatively small global harvested area of roughly 174,000 ha.

Tab. 3.2 Global sums of harvested area of irrigated crops (AIH), by crop, in ha $\mathrm{yr}^{-1}$

| Crop class | Crop name | AIH $\left[\mathrm{ha} \mathrm{yr}^{-1}\right]$ |
| :---: | :--- | ---: |
| 1 | Wheat | $66,632,213$ |
| 2 | Maize | $29,900,729$ |
| 3 | Rice | $103,119,737$ |
| 4 | Barley | $4,645,848$ |
| 5 | Rye | 442,273 |
| 6 | Millet | $1,743,733$ |
| 7 | Sorghum | $3,436,567$ |
| 8 | Soybeans | $6,032,664$ |
| 9 | Sunflower | $1,268,738$ |
| 10 | Potatoes | $3,745,498$ |
| 11 | Cassava | 11,195 |
| 12 | Sugar cane | $10,189,041$ |
| 13 | Sugar beet | $1,574,018$ |
| 14 | Oil palm | 11,000 |
| 15 | Rapeseed | $3,403,812$ |
| 16 | Groundnuts | $3,675,803$ |
| 17 | Pulses | $5,455,811$ |
| 18 | Citrus | $3,562,673$ |
| 19 | Date palm | 723,436 |
| 20 | Grapes | $1,726,687$ |
| 21 | Cotton | $16,252,240$ |
| 22 | Cocoa | 12,544 |
| 23 | Coffee | 173,916 |
| 24 | Others perennial | $12,852,980$ |
| 25 | Managed grassland | $11,684,007$ |
| 26 | Others annual | $20,138,737$ |

### 3.3 Annual cycle of global monthly growing areas of irrigated wheat, rice, maize, and cotton

The global sums of monthly irrigated growing area of 4 major selected crops (wheat, rice, maize, cotton) as compiled directly from the crop calendars and fully consistent to the MGAG-I (Tab. 2.3) show different annual cycles (Fig. 3.1). The rice cycle reflects multi-cropping in the major production regions, mainly Asia (see distribution in Fig. 3.4), while irrigated wheat production is predominantly winter wheat in Asia and North America (see distribution in Fig. 3.2). Maize and cotton are mainly grown during northern hemisphere summer.

Fig. 3.1 Global monthly growing areas of irrigated wheat, rice, maize, and cotton, in ha, for 1998-2002

### 3.4 Global maps of monthly growing areas of irrigated wheat, rice, maize, and cotton

## Wheat

The cropping seasons of irrigated wheat are distinctly recognisable (Fig. 3.2): Winter is the predominant time for cultivation of wheat, with sowing typically in autumn, and with harvest in early summer or mid-summer. In January, irrigated winter wheat is cultivated in Pakistan, India, China and the United States of America. In the USA, the growing areas are in effect irrigated in months later than January, but the wheat is already established. For July, in the northern hemisphere, the high percentage of irrigated spring wheat, in northern India, as well as in southern Europe and the Caucasus is clearly visible. In the southern part of the USA, the areas consist of winter season wheat not yet harvested or a mixture of winter wheat and spring wheat.

Fig. 3.2 Global distribution of growing area of irrigated wheat in January and July, as percentage of grid cell area, for 1998-2002

## Maize

Maize has a cropping season with a length between 80 and 140 days (Doorenbos and Kassam, 1979). Irrigated maize is cultivated on large areas in July in the northern hemisphere in Asia (e.g. northern and north-eastern China, India, Pakistan), southern Europe, Africa (mostly Egypt) and North America (USA, Mexico) (Fig. 3.3). In the tropics, it is irrigated in Indonesia and in Ecuador. In January, irrigated maize is established in the northern hemisphere only in south-eastern China and Vietnam. In the southern hemisphere, it is cultivated to a much lesser extent. Generally, maize is found in many countries and often it is cultivated as a rainfed crop.

Fig. 3.3 Global distribution of growing area of irrigated maize in January and July, as percentage of grid cell area, for 1998-2002

## Rice

Rice with a cropping season with a length between 90 and 150 days (Doorenbos and Kassam, 1979) is distinctly a summer crop: In July it is cultivated under irrigation in many countries in Europe (Italy, Spain), Africa (Nile delta and valley in Egypt, Sudan) and United States of America (Mississippi, Missouri, Louisiana), also in the Middle East (Iran, Iraq), Central Asia (e.g. Uzbekistan), and southern Asia (Bangladesh, China, India, Korea, Pakistan, Thailand, Vietnam) (Fig. 3.4). For the southern hemisphere outside the tropics (Ecuador, Indonesia), the large extent in Madagascar is prominent in July (winter) as well as in January (summer). In January, during northern hemisphere winter, rice is still intensively grown in Bangladesh, China, India, and Thailand. In southern Asia, e.g. in China and in India 2 or even 3 cropping seasons are common, leading to the highest cropping intensity of more than $100 \%$ for a single crop (see Annex E).

Fig. 3.4 Global distribution of growing area of irrigated rice in January and July, as percentage of grid cell area, for 1998-2002

## Cotton

Cotton with cropping seasons with a length between 150 and 180 days (Doorenbos and Kassam, 1979) has its greatest extent in July like rice, especially prominent in northern Pakistan, northwestern India (Punjab, Haryana) and the United States of America (Texas, California, Mississippi, Missouri, Louisiana). High intensities also exist in the central Asian states of Uzbekistan, Turkmenistan, and Tajikistan, but also in Greece and north-eastern Syria. In January, irrigated cotton is nearly exclusively established in Egypt and in southern India. In the southern hemisphere, it is nearly non-existing besides relatively small areas in Brazil (Fig. 3.5).

Fig. 3.5 Global distribution of growing area of irrigated cotton in January and July, as percentage of grid cell area, for 1998-2002

### 3.5 Global map of total irrigated harvested area

The global distribution of the total annual harvested area for all of the 26 food crops on the 5 arc minute by 5 arc minute grid shows a maximum irrigation cropping intensity with more than one cropping season per year in parts of Asia (Bangladesh, China, northern India, Indonesia, Pakistan, Thailand, and Vietnam) and Africa (Egypt) (Fig. 3.6). This is, to a great extent due to the double or triple cropping of rice sometimes also in combination with other crops. But high intensities also occur at specific places in some countries of Asia, the United States of America, especially in California and the Great Plains.

Fig. 3.6 Global distribution of harvested area of all irrigated crops, as percentage of grid cell area, for 1998-2002

In Annex E, the global distribution of harvested area for each of the 26 crop classes with more than 15,000 ha irrigated harvested area is shown. The list of irrigated harvested area (AIH) per entity is presented in Tab. B 1 in Annex B.

### 3.6 Validation and discussion

### 3.6.1 Sources of uncertainty

The uncertainty of the cell-specific growing areas of irrigated crops originates from two sources: the first one concerning the detailed and the Condensed Crop Calendars for irrigated crops (CC-I), and the second one concerning the Monthly Growing Area Grids of irrigated crops (MGAG-I), i.e. mainly the distribution algorithm of the CC-I areas to the grid cells.

## Uncertainties of the crop calendars

The uncertainties of the crop calendars are basically caused by uncertainties of the irrigated harvested area and the correctness of the start and end of the cropping season.

Concerning the harvested area, it was tried to gather data sets of the biggest possible reliability (see Chapter 2.1). At one hand, even the FAO AQUASTAT reports sometimes have only data from periods before the reference period 1998-2002. On the other hand, when crop classes in the original data had to be disaggregated or reclassified, some significant misclassifications or general errors could have been introduced. But it was tried to minimise these errors and to document in detail the used sources and procedures (see Annex C). A great uncertainty exists concerning the "other" crop classes, especially when broadly specified classes (e.g. root and tubers) of the original data were classified as "other" crops if no information was available to disaggregate or assign areas to one of the 26 own classes (e.g. potatoes and cassava). This leads to substantial harvested area in the classes of other annual crops and other perennial crops. Likewise, for managed grassland, often a HEREdistinction of broadly defined original classes as forage crops (to be classified possibly as a specific crop or as other annual crops) and grassland is difficult and sometimes it was done in favour of other annual crops. Also the distinction between pasture (to be excluded when used as rangeland outside cropland) and meadows as managed grassland (to be included) was often not clear in the original data.

Concerning the growing months, from a methodological point, the static calendars do not represent the year-to-year variability due to climatic factors, but average calendars. The crop calendars had to be simplified in terms of number of sub-crops (seasons) and in terms of start and end of seasons in order that the maximum of monthly irrigated area (MMIA) did not exceed AEI. When no calendar for irrigated crops with contrary information existed, as often as possible a cropping intensity of 1 was assumed and the start and end of cropping seasons with probably minor irrigated areas were suppressed or joined to longer cropping seasons. But also the information of the different sources was sometimes contradictory or unspecific. Therefore, the used procedures and the data sources are documented in detail in Annex C. In general, some assumptions made on the main irrigation months helped to establish new calendars from information of neighbouring countries. When the information like that from FAO GIEWS (FAO, 2005b) did not present any distinction between rainfed and irrigated crops, the establishment of seasons with supplementary irrigation was especially difficult and therefore was subject to possibly large errors. Only for countries or entities with arid climate the answer was easy to find, as all crops are irrigated there. Also for cereals like wheat, barley or rye whose spring varieties can be grown either in winter or in summer when the climate is favourable, it is difficult whether it was grown in the winter or summer season. Generally, in areas of severe winter, cold winds and little snow, spring wheat varieties are grown (Doorenbos and Kassam, 1979). The winter varieties need a cold period or chilling (so-called vernalization) during early growth for normal heading under long days, with a cropping season of 180-250 days up to maturity for wheat. In its early stages, winter wheat exhibits a strong resistance
to frost, down to $-20^{\circ} \mathrm{C}$. In general, it is assumed that for irrigated crops winter cereals are grown during winter (cold season), with sowing in autumn or after the last harvest and harvesting in summer of the following year, and that spring cereals (including durum wheat) are grown during summer, with sowing in spring and harvest in summer, as e.g. spring wheat does not require chilling for heading and is day-neutral, with a total cropping season from 100-130 days (Doorenbos and Kassam, 1979).

## Uncertainties of the MGAG-I distribution methodology

The principle of the consistency of the MGAG-I with the other input data is shown in Tab. 2.3. The MGAG-I are fully consistent to the CC-I, they are also mostly consistent to AEI (besides some necessary scaling), they are as much as possible consistent to the SAGE cropland extent and to the SAGE harvested area.

To test the added value of the complex distribution methodology described in Chapter 2.2.4 against a straightforward simple distribution, the CC-I cropping seasons were distributed to the grid cells with a proportional distribution of the AEI using the ratio of the monthly area and the AEI on entity level. The ratio was derived from the crop calendar for irrigated crops of the specific entity and corresponds to the share of AEI that the monthly growing area of the sub-crop has in the crop calendar for irrigated crops. As inconsistencies between the reference AEI used in the crop calendar and the sum of the cell-level AEI existed (Chapter 2.2.4, step 1), the sum of the cell-level AEI replaced the reference AEI as denominator in Eq. (7). In the simple distribution, this ratio was applied uniformly to all grid cells of the entity, without the distinctions made in steps 2-3 of the complex distribution. The resulting monthly area in the grid cell for the specific sub-crop was the AEI in the grid cell multiplied by the entity-level ratio:

$$
\begin{equation*}
\text { AGi(cell,subcrop,month })=\frac{A G i \_C C I(\text { entity }, \text { subcrop,_month })}{\sum_{\text {cells }} A E I(\text { cell, entity })} * A E I(\text { cell }) \tag{7}
\end{equation*}
$$

where $A G i($ (cell,subcrop,month) was the cell-specific growing area of the specific sub-crop in a given month, AGi_CCI(entity,subcrop,month) was the growing area of the specific sub-crop in a given month in the Condensed Crop Calendar for irrigated crops, $\sum_{\text {cells }} A E I$ (cell,entity) was the sum of the cellspecific AEI values, given for the considered entity. This equation ensured full consistency to the CC-I, and to the reference AEI used for the entity in the calendar AEI_CCI (monthly area actually irrigated AAI_CCI $\leq$ AEI_CCI) and to the cell-specific AEI (and sum per entity) of the Global Map of Irrigation Areas in the same way as the complex distribution.

First, the deviation of the MMIA from the (unscaled) AEI according to GMIA was computed following Equations (8) to (11). The cell-level monthly total irrigated area exceeding AEI corresponds to the area that should not have been distributed, as AEI should be a limiting factor. On a global scale, the excess area was smaller for the simple distribution ( $328,278 \mathrm{ha}$ ) than for the complex distribution ( $330,340 \mathrm{ha}$ ). These values correspond to about $0.12 \%$ of the total AEI of 278.9 Mha found in the original GMIA grid.

$$
\begin{equation*}
E X_{-} M M I A_{-} A E I(\text { global })=\sum_{\text {cells }} E X_{-} M M I A_{-} A E I(\text { cell }) \tag{8}
\end{equation*}
$$

with

$$
\begin{align*}
& E X_{-} M M I A_{-} A E I(c e l l)=\left\{\begin{array}{cc}
M M I A(c e l l)-A E I_{-} \text {unscaled }(c e l l) & \text { if } \quad M M I A(c e l l)>A E I_{-} \text {unscaled(cell) } \\
0 & \text { else }
\end{array}\right.  \tag{9}\\
& \operatorname{MMIA}(\text { cell })=\operatorname{MAX}\left(\sum_{\text {crops }} A G i_{-} m(1)(\text { cell }, \text { crop }), \ldots, \sum_{\text {crops }} A G i_{-} m(12)(\text { cell, crop })\right)  \tag{10}\\
& \sum_{\text {crops }} A G i_{-} m(k)(\text { cell,crop })=\sum_{\text {crops }, i}\left(\sum_{\text {subcrops }} A G i_{-} m(k)(\text { cell, subcrop })\right) \tag{11}
\end{align*}
$$

where EX_MMIA_AEI(global) is the global sum over all cells of EX_MMIA_AEI(cell), the cell-specific excess area where MMIA is larger than AEI. MMIA(cell) is the maximum of monthly irrigated areas. $\sum_{\text {crops }} A G i_{-} m(k)($ cell,crop $)$ is the cell-specific sum of irrigated growing area of all crops for month $k(\mathrm{k}=1, \ldots, 12), \sum_{\text {subcrops }} A G i_{-} m(k)($ cell, subcrop $)$ the cell-specific sum of irrigated growing area of all sub-crops of a given crop class for month $i$, AEI_unscaled(cell) is the unscaled cell-specific area equipped for irrigation of GMIA.

Next, the deviation of MMIA from the SAGE cropland extent on cell level was computed following Equations (12) to (13). The cell-level monthly area exceeding SAGE cropland extent corresponds to the area that should not have been distributed because cropland extent limitation. On a global scale, the excess area was larger for the simple distribution ( 30.2 Mha ) than for the complex distribution ( 26.7 Mha ), corresponding to $2.0 \%$ and $1.8 \%$ of the total cropland area of 1.5 Gha or $10.9 \%$ and $9.6 \%$ of the AEI.
$E X_{-} M M I A_{-} A C L($ global $)=\sum_{\text {cells }} E X_{-} M M I A_{-} A C L($ cell $)$
with
$E X \quad M M I A_{-} A C L(c e l l)=\left\{\begin{array}{cc}M M I A(c e l l)-A C L(c e l l) & \text { if } \\ 0 & \text { else }\end{array}\right.$
where $E X \_M M I A \_A C L$ (global) is the global sum over all cells of $E X \_M M I A \_A C L(c e l l)$, the cell-specific excess area where MMIA is larger than the cell-specific SAGE cropland extent ACL(cell).

These effects for the deviation of MMIA from unscaled AEI and cropland extent in the complex distribution are due to the distribution step 5 of the complex distribution where areas with AEI but without cropland are filled when the SAGE harvested area does not meet the requirements of the irrigated growing areas of the Condensed Crop Calendars. In some cases, this leads to a concentration of growing area in cells where no cropland exists. As a result, MMIA is high and also sums of MMIA in excess of AEI and of cropland extent are high. In contrast to this, the simple distribution of Equation (7) has a spatially smoother distribution of MMIA, as the growing areas are uniformly distributed over all grid cells with AEI. This results in smaller deviations of MMIA from AEI. The areas in excess of AEI are found for both distribution methods in the 30 entities where scaling was made during step 1 of the complex distribution, and implicitly in the simple distribution (Eq. 7). On the other hand, the simple distribution leads to larger deviation from the cropland extent than the complex one that considers the presence of cropland, because AEI and cropland extent often do not correspond.

The deviation of the distributed irrigated harvested area of each crop from the SAGE harvested area is given in form of the cell-level harvested areas which are larger than the reference value, corresponding to the area that should not have been distributed because limitation of the (irrigated and rainfed) SAGE harvested area (Eq. 14 and Eq. 15).

$$
\begin{equation*}
E X X_{-} A I H(\text { global }, \text { crop })=\sum_{\text {cells }} E X_{-} A I H(\text { cell }, \text { crop }) \tag{14}
\end{equation*}
$$

with

$$
E X_{-} A I H(\text { cell }, \text { crop })=\left\{\begin{array}{cc}
A H i(\text { cell }, \text { crop })-A H(\text { cell }, \text { crop }) & \text { if }  \tag{15}\\
0 & \text { else }
\end{array}\right.
$$

where $E X \_A I H(g l o b a l, c r o p)$ is the global sum over all cells of $E X \_A I H$ (cell, crop), the cell-specific excess area where the cell-specific irrigated harvested area $\mathrm{AHi}(c e l l$, crop) is larger than the (irrigated and rainfed) SAGE harvested area $A H$ (cell, crop), for each crop.

The values for the crop classes show the superiority of the complex method of Chapter 2.2.4 over the simple distribution (Tab. 3.3). On a global scale, over all crops, with the simple distribution $40 \%$ of the irrigated harvested area was distributed to cells without enough rainfed and irrigated SAGE harvested area. With the complex distribution, only $29 \%$ of the AIH was wrongly distributed, which was an improvement of $11 \%$ with respect to the AIH or roughly a $1 / 4$ of the area of the simple distribution.

With the complex distribution as the better one, most crops had excess harvested areas corresponding to between 20 and $35 \%$ of the AIH. Oil palm areas were fully consistent to the reference, and only up to about $10 \%$ wrongly distributed harvested area were observed for rapeseed, pulses, and coffee. This is certainly because much reference harvested area of SAGE existed where AEI was located, confirmed by excellent improvements for oil palms ( $88 \%$ ) and coffee ( $36 \%$ ) in comparison to the results of the simple distribution. For rapeseed the good agreement could be the consequence of the large concentration to India that is well covered to subnational level by 35 sub-national entities in MIRCA2000, by 552 sub-national units in the SAGE cropland extent (Ramankutty et al., 2008) and represented to $88 \%$ by sub-national data in the SAGE harvested area (Monfreda et al., 2008). Pulses are also cultivated to a large extent in India, USA, and Brazil where sub-national entities exist. Between 40 and $60 \%$ excess area was found for date palm, cocoa, sugar beets, and citrus. For citrus, this is a consequence of the lack of appropriate sub-national resolution of SAGE harvested area for southern Europe (see Chapter 3.6.4). The improvement of the complex distribution method over the simple method was not uniform. It was least for e.g. rye, soybeans, and other annual crops (all below about $10 \%$ ), which indicates that no or not enough reference SAGE harvested area in grid cells with AEI existed for these crops. For other annual crops, the complex distribution even leads to an increased deviation that is the at least partly the consequence of the treatment of this class as the last starting with distribution step 3.

Overall, for the most important crops with at least 10 Mha irrigated harvested area (rice, wheat, maize, cotton, sugar cane, other annual crops, other perennial crop and managed grassland) the congruence with SAGE harvested area is surprisingly small. For rice, whose distribution was expected to be mostly limited to areas equipped for irrigation, still roughly $30 \%$ of the total irrigated harvested area are in excess of cell-level SAGE harvested area, for cotton even $39 \%$. Perhaps this is due to cells with a concentration of growing areas in distribution step 5.

Tab. 3.3 Cell-level MGAG-I harvested areas exceeding the (rainfed and irrigated) SAGE harvested area, using simple and complex distribution methods

| Crop class | Crop name | $\begin{array}{r} \text { AIH } \\ {\left[\mathrm{ha} \mathrm{yr}^{-1}\right]} \end{array}$ | $\begin{aligned} & \text { EX_AIH_S } \\ & {[\% \text { of AIH] }} \end{aligned}$ | $\begin{gathered} \text { EX_AIH_C } \\ {[\% \text { of AIH] }} \end{gathered}$ | EX_AIH_S - EX_AIH_C $[\%$ of AIH $]$ |
| :---: | :---: | :---: | :---: | :---: | :---: |

| EX_AIH_S - EX_A | $=$ Improvement of the deviations through the complex distribution method, calculated as difference of EX AIH S and EX AIH C, in percentage points of AIH. |  |  |  |  |

### 3.6.2 Sub-national data

Sub-national data enable a much more detailed view on the distribution of crops. This is demonstrated for the United States of America (Fig. 3.7), where sub-national data of 51 states show as distinct cuts of different cropping intensity in the central part of the USA along the state boundaries between Nebraska and Kansas along the $40^{\circ} \mathrm{N}$ parallel, and between the states of Mississippi, Arkansas and Missouri along the Mississippi River. If the USA were treated as only one entity, the distribution would be smoother without these cuts, but certainly at the expense of the congruence with the reference SAGE harvested area on state level.

Fig. 3.7 Distribution of irrigated harvested area in the USA, as percentage of grid cell area, for 1998-2002

### 3.6.3 Case study Egypt

In Egypt, the results of the complex distribution methodology under the conditions of almost exclusively irrigation-based agriculture can be studied. The FAO Africover database (FAO, 2007b) was used as reference data set that provided polygon data of the agricultural plots, together with information on crops grown there. Two types of growing areas, main areas and possible secondary areas, were extracted from this reference for wheat, cotton, and rice. For cotton and wheat, the reference data show the limits of the main cultivation fields used for cultivation of both crops, and also the borders of other unspecific herbaceous crops. For rice-specific growing areas are delineated in Africover, and other areas permanently used that could be potentially cropped with rice.

In the MGAG-I data set, 1.0 million ha harvested area of wheat was distributed in the complex distribution described in Chapter 2.2.4 for the months of November to March, before rice with 650,000 ha for June to October and cotton with 145,000 ha for July to January, all with one cropping season.

Wheat in MGAG-I is most intensively grown in the delta and the valley of the River Nile, confirmed by the distribution of major wheat/cotton fields in Africover. Minor or marginal harvested areas of MGAG-I occur (1) at the edges of the cultivated land of the delta and the Mediterranean coast towards the desert or (2) at oasis locations all over Egypt where Africover indicates other herbaceous crops (Fig. 3.8). The congruence with the reference data is good.

Rice harvested areas in MGAG-I are concentrated in the River Nile delta, where specific growing areas are mentioned in Africover. But distinct areas are also found at the sides of the River Nile valley, where beyond the wheat/cotton fields also permanently used fields are located. The congruence with the reference data is excellent.

Cotton was distributed after wheat and rice. Its major harvested areas in MGAG-I correspond to fields where cotton and wheat are mixed in Africover. But a much larger share of areas than for wheat is located in unspecific fields of Africover, so that the congruence with the reference data is much smaller than for wheat. This was first because the SAGE harvested area was zero where AEI was located, and next because the crop was distributed when other crops like wheat or rice had already occupied space in months where also cotton was potentially grown. As a consequence, the needed rest area was distributed to areas equipped for irrigation where other crops left free space. This is the case for areas in the west at the Mediterranean coast and also in the desert.

Fig. 3.8 Case study Egypt: Distribution of irrigated harvested area and reference data of Africover, for wheat, rice, cotton, for 1998-2002

### 3.6.4 Case study Europe

For Europe, the results of the complex distribution methodology for agriculture under irrigated and rainfed conditions are demonstrated, and the accuracy of the distribution made from national-level data was tested with independent data on sub-national level. EUROSTAT sub-national data on maize, soybeans, sunflower, potatoes, sugar beets, citrus, and grapes, the crops which are also contained in the list of crop classes of the MGAG-I data set (Tab. 2.1), were used as reference data (EUROSTAT, 2007). Other not fully compatible crop classes used by this source were durum wheat, fruits and berry orchards, and fodder. Area irrigated once a year of each crop for administrative units down to NUTS level 2 were available for Austria (level of regions), France (departments), Greece, Hungary, Italy (provinces), Slovakia, Spain (provinces). Unfortunately, sometimes values were missing for some sub-national units, e.g. often for Andalusia in Spain. Also zero values were possibly indicating no data, too. The distribution of maize, grapes, and citrus was taken as an example for the data quality.

## Maize

When comparing maize area in MGAG-I with EUROSTAT maize area irrigated once a year, the fit is excellent or good for France, northern and central Italy (besides Sicily), Greece (besides the island of Crete), Hungary, and Portugal (Fig. 3.9). In Spain, the correlation is bad in the provinces of Murcia and Valencia, where EUROSTAT did not report irrigated area. This indicates that maize is growing there as a rainfed crop.

Fig. 3.9 Case study Europe: Distribution of harvested area and reference data of EUROSTAT, for irrigated maize, for 1998-2002 and for 2003, respectively

## Grapes

For grapes, also harvested once a year like maize, the distribution of harvested area in MGAG-I and according to EUROSTAT fit excellently or well for Austria, France, northern and central Italy (besides Puglia and Sicily), Greece (also on the island of Crete), Spain, and Portugal (Fig. 3.10).

Fig. 3.10 Case study Europe: Distribution of harvested area and reference data of EUROSTAT, for irrigated grapes, for 1998-2002 and for 2003, respectively

## Citrus

For citrus, the distribution of harvested area in MGAG-I and according to EUROSTAT fit generally bad for all of the concerned countries (Italy, Greece, Spain, and Portugal) (Fig. 3.11). The MGAG-I area follows the distribution of the SAGE harvested area that is more uniformly distributed in those countries (not shown here). This indicates that irrigated citrus is grown in general only along the Mediterranean coast, while it is rainfed in the other regions. The methodology to distribute crops that was used here failed to separate those rainfed and irrigated zones for specific crops. This highlights that it is required to increase the density of entities in those regions.

Fig. 3.11 Case study Europe: Distribution of harvested area and reference data of EUROSTAT, for irrigated citrus, for 1998-2002 and for 2003, respectively

## 4. Summary and outlook

An ample data set of Monthly Growing Area Grids (MGAG-I) of 26 irrigated crops and related crop calendars (CC-I) for 402 spatial entities was compiled. The selection of the crops includes all major food crops including regionally important ones (wheat, rice, maize, barley, rye, millet, sorghum, soybeans, sunflower, potatoes, cassava, sugar cane, sugar beets, oil palm, rapeseed/canola, groundnuts/peanuts, pulses, citrus, date palm, grapes/vine, cocoa, coffee), major water-consuming crops (cotton), and unspecified other crops (other perennial crops, other annual crops, managed grassland). The data set refers to the time period 1998-2002, depicting the present extent of irrigated crops.

For the compilation, it was tried to maximise consistency of the crop calendars and the grids with validated FAO AQUASTAT information and national statistics on irrigation. MGAG-I and CC-I are fully consistent on entity level. For other input data, the consistency on cell level was calculated. Globally, the cell-level maximum monthly excess of MGAG-I as compared to the AEI of the Global Map of Irrigation Areas is 330,340 ha or only about $0.12 \%$ of the global AEI of 278.9 Mha found in the original grid. The respective maximum monthly excess area as compared to the SAGE cropland extent is 26.7 Mha , corresponding to about $1.8 \%$ of the total cropland area. The mean deviation of the distributed MGAG-I harvested area from the reference SAGE harvested area is $29 \%$ of the AIH, or $31.9 \%$ of the AEI.

It was shown that the chosen complex distribution method enhanced the congruence of the harvested area with the reference SAGE harvested area.

The data set can be used for global and continental-scale studies on food security and water use. Nevertheless, the water demand cannot be derived in a $1: 1$ relationship from the growing area, as winter wheat areas during cold winter months have small or non-existing actual evapotranspiration.

The second part of the Global data set of monthly irrigated and rainfed crop areas around the year 2000 (MIRCA2000), a consistent data set for rainfed crops with respective Monthly Growing Area Grids of rainfed crops (MGAG-R) and crop calendars for rainfed crops (CC-R) is already compiled and will be published separately.

The complete data set will then be used to calculate water use on a global and continental scale to assess the stress on different sources of water.

In the future, the data set will be improved, e.g. with a better spatial resolution of crop calendars and an improved crop distribution algorithm. The MIRCA2000 data set, its full documentation together with future updates will be freely available through an internet site (http://www.geo.uni-frankfurt.de/ipg/ag/dl/forschung/MIRCA/index.html).

## Annex A: Example of the distribution of monthly growing areas of irrigated crops in calendars to grid cells for a hypothetic entity

The procedure how the monthly growing areas of irrigated crops of the Condensed Crop Calendars are distributed to specific grid cells (see Chapter 2.2.4) is illustrated in this Annex by using a hypothetic example belonging to a fictitious entity.

The entity consists of 4 grid cells arranged in a 2 by 2 grid. In the following, the upper left grid cell is referred to as grid cell number 1, the upper right cell as grid cell 2, the lower left cell as grid cell 3 and the lower right cell as grid cell 4 . The total cell area of each cell is assumed to be $10,000 \mathrm{ha}$. The following data of growing areas of irrigated rice, oil palm, other perennial crops, and maize were derived from the input data sets:

Tab. A 1: Sub-crops with their cropping season derived from the Condensed Crop Calendar for irrigated crops

| Sub-crop | Start and end of the cropping season <br> [month of the year] | Growing area [ha] |
| :--- | :---: | ---: |
| Rice 1 | $4-7$ | 12,000 |
| Rice 2 | $8-11$ | 7,000 |
| Oil palm | $1-12$ | 100 |
| Others perennial | $1-12$ | 50 |
| Maize 1 | $3-7$ | 600 |
| Maize 2 | $8-2$ | 150 |

Total harvested area of the 6 sub-crops is 19,900 ha, with 2 cropping seasons for rice (in total 19,000 ha harvested area) and maize (in total 750 ha harvested area).

Fig. A 1: Area equipped for irrigation (AEI)
per grid cell in ha (theoretical source: GMIA)

| 6,000 | 8,000 |
| :---: | :---: |
| 2,000 | 0 |

Fig. A 2: Cropland extent per grid cell in ha (theoretical source:
SAGE cropland extent)

| 5,000 | 9,000 |
| :---: | :---: |
| 0 | 4,000 |

AEI and cropland extent are unevenly distributed (Figs. A 1 and A 2). In cell 3 AEI exists but no cropland is given, and in cell 4 no AEI is given while cropland exists. This means, that in cell 4 only rainfed agriculture is practised. While rice, other perennial crops and maize have (irrigated and rainfed) SAGE harvested area in all cells with cropland, oil palm has SAGE harvested area only in cell 4.

Fig. A 3: Harvested area for each crop (AH) per grid cell in ha, shown only for crop classes that are at least partly irrigated (theoretical source: SAGE harvested area)

| Rice: 6,000 <br> Oil Palm: 0 <br> Others perennial: 1,000 <br> Maize: 200 <br> AH total: 8,000 | Rice: 12,000 <br> Oil Palm: 0 <br> Others perennial: 1,500 <br> Maize: 300 <br> AH total: 15,000 |
| :---: | :---: |
| Rice: 0 <br> Oil Palm: 0 <br> Others perennial: 0 <br> Maize: 0 <br> AH total: 0 | Rice: 2,500 <br> Oil Palm: 300 <br> Others perennial: 750 <br> Maize: 200 <br> AH total: 5,000 |

## Step 1:

For the example given, it was not necessary to change the AEI by scaling.

## Step 2:

a) Computing of AGi_base (in ha) for all cells and irrigated crops:

Tab. A 2: Computing of preliminary base growing area in distribution step 2

| Crop | AGi_base cell 1 | AGi_base cell 2 | AGi_base cell 3 | AGi_base cell 4 | AGi_base in entity (preliminary) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Rice | $\begin{aligned} & =\frac{6000}{2} * \frac{6000}{10000} \\ & =1800 \end{aligned}$ | $\begin{aligned} & =\frac{12000}{2} * \frac{8000}{10000} \\ & =4800 \end{aligned}$ | $\begin{aligned} & =\frac{0}{2} * \frac{2000}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =\frac{2500}{2} * \frac{0}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =1800+4800+0+0 \\ & =6600 \end{aligned}$ |
| Oil palm | $\begin{aligned} & =\frac{0}{1} * \frac{6000}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =\frac{0}{1} * \frac{8000}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =\frac{0}{1} * \frac{2000}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =\frac{300}{1} * \frac{0}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =0+0+0+0 \\ & =0 \end{aligned}$ |
| Others perennial | $\begin{aligned} & =\frac{1000}{1} * \frac{6000}{10000} \\ & =600 \end{aligned}$ | $\begin{aligned} & =\frac{1500}{1} * \frac{8000}{10000} \\ & =1200 \end{aligned}$ | $\begin{aligned} & =\frac{0}{1} * \frac{2000}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =\frac{750}{1} * \frac{0}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =600+1200+0+0 \\ & =1800 \end{aligned}$ |
| Maize | $\begin{aligned} & =\frac{200}{2} * \frac{6000}{10000} \\ & =60 \end{aligned}$ | $\begin{aligned} & =\frac{300}{2} * \frac{8000}{10000} \\ & =120 \end{aligned}$ | $\begin{aligned} & =\frac{0}{2} * \frac{2000}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =\frac{200}{2} * \frac{0}{10000} \\ & =0 \end{aligned}$ | $\begin{aligned} & =60+120+0+0 \\ & =180 \end{aligned}$ |

b) Checking whether scaling to minimum of sub-crop growing areas is necessary:

Rice: $\quad 6600<\min (12000,7000) \quad \Rightarrow$ scaling not necessary
Oil palm: $\quad 0<100 \quad \Rightarrow$ scaling not necessary
Others perennial: $1800>50$
Maize: $\quad 180>\min (600,150)$

$$
\Rightarrow \text { scaling necessary, scaling coefficient }=50 / 1800
$$

$\Rightarrow$ scaling necessary, scaling coefficient $=150 / 180$
c) Scaling of base growing areas:

Tab. A 3: Computing of scaled base growing area in distribution step 2

| Crop | AGi_base cell 1 | AGi_base cell 2 | AGi_base cell 3 | AGi_base cell 4 | AGi_base in entity (scaled) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Rice | $=1800$ | $=4800$ | $=0$ | $=0$ | $=6600$ |
| Oil palm | $=0$ | = 0 | $=0$ | $=0$ | $=0$ |
| Others perennial | $\begin{aligned} & =600 * \frac{50}{1800} \\ & =16.67 \end{aligned}$ | $\begin{aligned} & =1200 * \frac{50}{1800} \\ & =33.33 \end{aligned}$ | $\begin{aligned} & =0 * \frac{50}{1800} \\ & =0 \end{aligned}$ | $\begin{aligned} & =0 * \frac{50}{1800} \\ & =0 \end{aligned}$ | $\begin{aligned} & =16.67+33.33+0+0 \\ & =50 \end{aligned}$ |
| Maize | $\begin{aligned} & =60 * \frac{150}{180} \\ & =50 \end{aligned}$ | $\begin{aligned} & =120 * \frac{150}{180} \\ & =100 \end{aligned}$ | $\begin{aligned} & =0 * \frac{150}{180} \\ & =0 \end{aligned}$ | $\begin{aligned} & =0 * \frac{150}{180} \\ & =0 \end{aligned}$ | $\begin{aligned} & =50+100+0+0 \\ & =150 \end{aligned}$ |

The monthly growing areas (in ha) and the area harvested ( AH , in ha $\mathrm{yr}^{-1}$ ) of irrigated crops distributed at the end of step 2 to the grid cells are:

Tab. A 4: Monthly growing areas after distribution step 2
Cell 1:

| Month | Rice | Oil palm | Others perennial | Maize | Total |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 0 | 0 | 16.67 | 50 | 66.67 |
| 2 | 0 | 0 | 16.67 | 50 | 66.67 |
| 3 | 0 | 0 | 16.67 | 50 | 66.67 |
| 4 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 5 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 6 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 7 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 8 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 9 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 10 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 11 | 1800 | 0 | 16.67 | 50 | 1866.67 |
| 12 | 0 | 0 | 16.67 | 50 | 66.67 |
| AH | 3600 | 0 | 16.67 | 100 | 3716.67 |

Cell 2:

| Month | Rice | Oil palm | Others perennial | Maize | Total |
| ---: | ---: | ---: | ---: | ---: | ---: |

| 4 | 0 | 0 | 0 | 0 | 0 |
| 5 | 0 | 0 | 0 | 0 | 0 |
| 6 | 0 | 0 | 0 | 0 | 0 |
| 7 | 0 | 0 | 0 | 0 | 0 |
| 8 | 0 | 0 | 0 | 0 | 0 |
| 9 | 0 | 0 | 0 | 0 | 0 |
| 10 | 0 | 0 | 0 | 0 | 0 |
| 11 | 0 | 0 | 0 | 0 | 0 |
| 12 | 0 | 0 | 0 | 0 | 0 |
| AH | 0 | 0 | 0 | 0 | 0 |

## Results after step 2:

- For all crops together, 13,550 ha $\mathrm{yr}^{-1}$ out of the $19,900 \mathrm{ha} \mathrm{yr}^{-1}$ total harvested area were distributed to grid cells in step 2.
- The growing areas for the sub-crops 'Others perennial' and 'Maize 2' were completely distributed to the grid cells in step 2 . Therefore, these sub-crops don't need to be processed with distribution steps 3-6.

From step 3 onwards the order in which the remaining sub-crops need to be processed depends on the criteria described in Chapter 2.2.4. In the example given here, the order is as follows: Oil palm (permanent crop) $\Rightarrow>$ Rice 1 (Rice has largest harvested area, Rice 1 has larger growing area than Rice 2) $=>$ Rice $2=>$ Maize 1 (Maize has second largest harvested area).

## Oil palm, one cropping season, growing area 100 ha, months 1-12:

## Oil palm, Step 3:

Calculation of AEI_free(cell) according to Equation (3.1):

```
AEI_free(cell_1) = 6000 - max(66.67, 66.67, 66.67, 1866.67, 1866.67, 1866.67, 1866.67, 1866.67, 1866.67, 1866.67,
        1866.67,66.67) = 6000-1866.67 = 4133.33
AEI_free(cell_2) = 8000 - max(133.33, 133.33, 133.33, 4933.33, 4933.33, 4933.33, 4933.33, 4933.33, 4933.33,
    4933.33, 4933.33, 133.33) = 8000-4933.33 = \underline{3066.67}
AEI_free(cell_3) = 2000-\operatorname{max}(0,0,0,0,0,0,0,0,0,0,0,0)=2000-0=\underline{2000}
AEI_free(cell_4) = 0 - max (0, 0, 0, 0,0,0,0,0,0,0,0,0)=0-0=\underline{0}
```

Calculation of AH_free(cell,subcrop) according to Equations (3.2) and (3.3):

| AH_free(cell_1) | = $\underline{0}$ | (condition $\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}($ cell, crop) $>$ AGi_base(cell, crop) i.e. $(0>0)$ is false) |
| :---: | :---: | :---: |
| AH_free(cell_2) | $=\underline{0}$ | (condition $\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}($ cell, crop) $>$ AGi_base(cell, crop) i.e. $(0>0)$ is false) |
| AH_free(cell_3) | = $\underline{0}$ | (condition $\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}($ cell, crop) $>$ AGi_base(cell, crop) i.e. $(0>0)$ is false) |
| AH_free(cell_4) | $=(1 / 1) * 300-0=\underline{300}$ | (condition $\mathrm{ci}_{\mathrm{i}}$ * $\mathrm{AH}($ cell, crop) $>$ AGi_base(cell, crop) is true) |

Calculation of AGi3_to_distribute(entity,subcrop) according to Equation (3.4):
AGi3_to_distribute(entity) $=100-0=\underline{100}$
Calculation of AGi3_pot(cell,subcrop) according to Equation (3.6):

```
AGi3_pot(cell_1) = min}(4133.33,0)=\underline{0
AGi3_pot(cell_2) = min}(3066.67,0)=\underline{0
AGi3_pot(cell_3) = min}(2000,0)=\underline{0
AGi3_pot(cell_4) = min}(0,300)=\underline{0
```

Calculation of AGi3_pot(entity,subcrop) according to Equation (3.5):
AGi3_pot(entity) $=0+0+0+0=\underline{0}$
Calculation of $f 3$ (entity,subcrop) according to Equation (3.8):
f3(entity) $\quad=\underline{1} \quad$ (Remark: as AGi3_to_distribute(entity) $>$ AGi3_pot(entity))
Calculation of AGi3(cell,subcrop) according to Equation (3.7):

```
AGi3(cell_1) = 1 * 0= \underline{0}
AGi3(cell_2) = 1*0=\underline{0}
AGi3(cell_3) = 1*0=\underline{0}
AGi3(cell_4) = 1 * 0=\underline{0}
```

## Results for Oil palm after step 3:

- No growing area of sub-crop 'Oil palm' was distributed in step 3. Therefore the monthly growing areas distributed to the grid cells did not change. It is necessary to perform step 4.

## Oil palm, Step 4:

Calculation of AEI_free(cell) according to Equation (4.1):
The cropland extent $A C L(c e l l)$ has to be considered, and also the free harvested area AH_free(cell_1) and whether the cell has AEI or not:

| ACL(cell_1) | $=5000$ | (condition ACL(cell) $>0$ is true) |
| :---: | :---: | :---: |
| ACL(cell_2) | $=9000$ | (condition ACL(cell) $>0$ is true) |
| ACL(cell_3) | $=0$ | (condition ACL (cell) $>0$ is false) |
| ACL(cell_4) | $=5000$ | (condition ACL (cell) $>0$ is true) |
| AH_free(cell_1) | $=0$ | (condition AH_free $=0$ is true) |
| AH_free(cell_2) | 0 | (condition AH_free $=0$ is true) |
| AH_free(cell_3) | $=0$ | (condition AH_free $=0$ is true) |
| AH_free(cell_4) | $=300$ | (condition AH_free $=0$ is false) |

As only for cells 1 and cells 2 all necessary conditions are fulfilled, they receive a share of the free AEI, and the other cells do not. The calculation of AEI_free(cell) according to Equation (4.1) results in:

```
AEI_free(cell_1) = 6000 - max(66.67, 66.67, 66.67, 1866.67, 1866.67, 1866.67, 1866.67, 1866.67, 1866.67,
    1866.67, 1866.67,66.67) = 6000-1866.67 = 4133.33
AEI_free(cell_2) = 8000 - max(133.33, 133.33, 133.33, 4933.33, 4933.33, 4933.33, 4933.33, 4933.33, 4933.33,
    4933.33, 4933.33, 133.33) = 8000-4933.33 = \underline{3066.67}
AEI_free(cell_3) = \underline{0} (condition ACL(cell) >0 is false)
AEI_free(cell_4) = \underline{0} (condition AH_free = 0 is false)
```

Calculation of AGi4_to_distribute(entity,subcrop) according to Equation (4.2):
AGi4_to_distribute(entity) $=100-0=\underline{100}$
Calculation of AGi4_pot(cell,subcrop) according to Equation (4.4):

```
AGi4_pot(cell_1) = AEI_free(cell_1) \(=4133.33\)
AGi4_pot(cell_2) = AEI_free(cell_2) \(=3066.67\)
AGi4_pot \((\) cell_3) \(=\) AEI_free \((\) cell_3 \()=\underline{0}\)
AGi4_pot(cell_4) =AEI_free \((\) cell_4) \(=\underline{0}\)
```

Calculation of AGi4_pot(entity,subcrop) according to Equation (4.3):
AGi4_pot(entity) $=4133.33+3066.67+0+0=\underline{7200}$
Calculation of f4(entity,subcrop) according to Equation (4.6):
f4(entity) $\quad=\frac{100}{7200}$

Calculation of AGi4(cell,subcrop) according to Equation (4.5):
AGi4(cell_1) $\quad=(100 / 7200) * 4133.33=\underline{57.41}$
AGi4(cell_2) $\quad=(100 / 7200) * 3066.67=\underline{42.59}$
AGi4(cell_3) $=(100 / 7200) * 0=\underline{0}$
AGi4(cell_4) $=(100 / 7200) * 0=\underline{0}$
The monthly growing areas (in ha) and the area harvested ( AH , in ha $\mathrm{yr}^{-1}$ ) of irrigated crops distributed to the grid cells are as follows after Oil palm, step 4:
Tab. A 5: Monthly growing areas after distribution step 4 of Oil palm
Cell 1:

| Month | Rice | Oil palm | Others perennial | Maize | Total |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 0 | 57.41 | 16.67 | 50 | 124.08 |
| 2 | 0 | 57.41 | 16.67 | 50 | 124.08 |

## Results for Oil palm after step 4:

- The growing area of 'Oil palm' (100 ha) was completely distributed to the grid cells in step 4.
- Steps 5 and 6 are not necessary for 'Oil palm', therefore we proceed with the next priority crop rice and the sub-crop 'Rice 1' that has the largest irrigated harvested area of the rice sub-crops.

## Rice $1,1^{\text {st }}$ of 2 sub-crops, growing area 12,000 ha, months 4-7:

## Rice 1, Step 3:

Calculation of AEI_free(cell) according to Equation (3.1):

| AEI_free(cell_1) | $=6000-\max (1924.08,1924.08,1924.08,1924.08)=6000-1924.08=\underline{4075.92}$ |
| :--- | :--- |
| AEI_free(cell_2) | $=8000-\max (4975.92,4975.92,4975.92,4975.92)=8000-4975.92=\underline{3024.08}$ |
| AEI_free(cell_3) | $=2000-\max (0,0,0,0)=2000-0=\underline{2000}$ |
| AEI_free(cell_4) | $=0-\max (0,0,0,0)=0-0=\underline{0}$ |

Calculation of AH_free(cell,subcrop) according to Equations (3.2) and (3.3):

```
AH_free(cell_1) \(=(1 / 2) * 6000-1800=3000-1800=\underline{1200}\)
AH_free(cell_2) \(=(1 / 2) * 12000-4800=6000-4800=\underline{1200}\)
AH_free(cell_3) = \(\underline{0}\)
AH_free(cell_4) \(=(1 / 2) * 2500-0=1250-0=\underline{1250}\)
``` AGi_base(cell,crop) is true) (condition \(\mathrm{ci}_{\mathrm{i}}\) *AH(cell, crop) \(>\) AGi_base(cell,crop) is true) (condition \(\mathrm{ci}_{\mathrm{i}}\) *AH(cell, crop) \(>\) AGi_base(cell,crop) i.e. \((0>0)\) is false) (condition cii \({ }^{*}\) AH (cell, crop) \(>\) AGi_base(cell,crop) is true)

Calculation of AGi3_to_distribute(entity,subcrop) according to Equation (3.4):
AGi3_to_distribute(entity) \(=12000-6600=\underline{5400}\)
Calculation of AGi3_pot(cell,subcrop) according to Equation (3.6):
```

AGi3_pot(cell_1) $=\min (4075.92,1200)=\underline{1200}$
AGi3_pot $($ cell_2 $)=\min (3024.08,1200)=\underline{1200}$
AGi3_pot $($ cell_3) $=\min (2000,0)=\underline{0}$
AGi3_pot $($ cell_4 $)=\min (0,1250)=\underline{0}$

```

Calculation of AGi3_pot(entity,subcrop) according to Equation (3.5):
```

AGi3_pot(entity) = 1200+1200+0+0=2400

```

Calculation of \(f 3\) (entity,subcrop) according to Equation (3.8):
f3(entity) \(\quad=\underline{1} \quad\) (Remark: as AGi3_to_distribute(entity) \(>\) AGi3_pot(entity))
Calculation of AGi3(cell,subcrop) according to Equation (3.7):
```

AGi3(cell_1) = 1* 1200=1200
AGi3(cell_2) = 1*1200=1200
AGi3(cell_3) = 1* 0= 娄
AGi3(cell_4) = 1*0=0

```

The monthly growing areas (in ha) and the area harvested ( AH , in ha \(\mathrm{yr}^{-1}\) ) of irrigated crops distributed to the grid cells are as follows after Rice 1, step 3:

Tab. A 6: Monthly growing areas after distribution step 3 of Rice 1
Cell 1:
\begin{tabular}{rrrrrr}
\hline Month & Rice & Oil palm & Others perennial & Maize & Total \\
\hline 1 & 0 & 57.41 & 16.67 & 50 & 124.08 \\

\section*{Results for Rice 1 after step 3:}
- In total 9,000 ha out of the 12,000 ha growing area of 'Rice 1 ' was distributed to the grid cells at the end of step 5 .
- Step 4 is necessary for 'Rice \(1^{1}\).

\section*{Rice 1, Step 4:}

Calculation of AEI_free(cell) according to Equation (4.1):
```

AEI_free(cell_1) = 0}\mathrm{ (condition AH_free =0 is false)
AEI_free(cell_2) = 0 (condition AH_free =0 is false)
AEI_free(cell_3) = 0}\quad\mathrm{ (condition ACD}(cell)>0 is false)
AEI_free(cell_4) = 0 (condition AH_free =0 is false)

```

Calculation of AGi4_to_distribute(entity,subcrop) according to Equation (4.2):
AGi4_to_distribute(entity) \(=12000-9000=\underline{3000}\)
Calculation of AGi4_pot(cell,subcrop) according to Equation (4.4):
```

AGi4_pot(cell_1) = AEI_free(cell_1) = 0
AGi4_pot(cell_2) = AEI_free(cell_2) = 0
AGi4_pot(cell_3) = AEI_free(cell_3) = 0
AGi4_pot(cell_4) = AEI_free(cell_4) = 0

```

Calculation of AGi4_pot(entity,subcrop) according to Equation (4.3):
AGi4_pot(entity) \(=0+0+0+0=\underline{0}\)
Calculation of \(f 4\) (entity,subcrop) according to Equation (4.6):
f4(entity) \(\quad=1 \quad\) (Remark: as AGi4_to_distribute(entity) > AGi4_pot(entity))
Calculation of AGi4(cell,subcrop) according to Equation (4.5):
```

AGi4(cell_1) = 1 * 0= 教
AGi4(cell_2) = 1*0=0
AGi4(cell_3) = 1*0=0
AGi4(cell_4) = 1*0 = 0

```

\section*{Results for Rice 1 after step 4:}
- No growing area was distributed to 'Rice 1' in step 4. Therefore the monthly growing areas distributed to the grid cells did not change.
- Step 5 is necessary for 'Rice 1'.

\section*{Rice 1, Step 5:}

Calculation of AEI_free(cell) according to Equation (5.1):
\begin{tabular}{lll} 
AEI_free(cell_1) & \(=\underline{0}\) & \\
(condition ACL(cell) \(=0\) is false) \\
AEI_free(cell_2) & \(=\underline{0}\) & (condition ACL(cell) \(=0\) is false) \\
AEI_free(cell_3) & \(=2000-\max (0,0,0,0)=2000-0=\underline{2000}\) & (condition ACL(cell) \(=0\) is true) \\
AEI_free(cell_4) & \(=\underline{0}\) & \\
(condition ACL(cell) \(=0\) is false)
\end{tabular}

Calculation of AGi5_to_distribute(entity,subcrop) according to Equation (5.2):
AGi5_to_distribute(entity) \(\quad=12000-9000=\underline{3000}\)
Calculation of AGi5_pot(entity,subcrop) according to Equation (5.3):
AGi5_pot(entity) \(=0+0+2000+0=\underline{2000}\)
Calculation of 95 (entity,subcrop) according to Equation (5.5):
f5(entity) \(\quad=1 \quad\) (Remark: as AGi5_to_distribute(entity) \(>\) AGi5_pot(entity))

Calculation of AGi5(cell,subcrop) according to Equation (5.4):
```

AGi5(cell_1) = 1*0 = 0
AGi5(cell_2) = 1*0=0
AGi5(cell_3) = 1*2000 = 2000
AGi5(cell_4) = 1*0= 人

```

The monthly growing areas (in ha) and the area harvested ( AH , in ha \(\mathrm{yr}^{-1}\) ) of irrigated crops distributed to the grid cells are as follows after Rice 1, step 5:
Tab. A 7: Monthly growing areas after distribution step 5 of Rice 1
Cell 1:
\begin{tabular}{rrrrrr}
\hline Month & Rice & Oil palm & Others perennial & Maize & Total \\
\hline 1 & 0 & 57.41 & 16.67 & 50 & 124.08 \\

\section*{Results for Rice 1 after step 5:}
- In total 11,000 ha out of the 12,000 ha growing area of 'Rice 1 ' was distributed to the grid cells at the end of step 5 .
- \(\quad\) Step 6 is necessary for 'Rice 1 '.

\section*{Rice 1, Step 6:}

Calculation of AEI_free(cell) according to Equation (3.1):
AEI_free(cell_1) \(=6000-\max (3124.08,3124.08,3124.08,3124.08)=6000-3124.08=\underline{2875.92}\)
AEI_free(cell_2) \(=8000-\max (6175.92,6175.92,6175.92,6175.92)=8000-6175.92=\underline{1824.08}\)
AEI_free(cell_3) \(=2000-\max (2000,2000,2000,2000)=2000-0=\underline{0}\)
AEI_free(cell_4) \(=0-\max (0,0,0,0)=0-0=\underline{0}\)
Calculation of AGi5_to_distribute(entity,subcrop) according to Equation (6.1):
AGi6_to_distribute(entity) \(\quad=12000-11000=\underline{1000}\)
Calculation of AGi6_pot(entity,subcrop) according to Equation (6.2):
AGi6_pot(entity) \(=2875.92+1824.08+0+0=\underline{4700}\)
Calculation of 45 (entity,subcrop) according to Equation (6.4):
f6(entity) \(\quad=\frac{1000}{4700}\)
Calculation of AGi6(cell,subcrop) according to Equation (6.3):
\begin{tabular}{ll} 
AGi6(cell_1) & \(=(1000 / 4700) * 2875.92=\underline{611.90}\) \\
AGi6(cell_2) & \(=(1000 / 4700) * 1824.08=\underline{388.10}\) \\
AGi6(cell_3) & \(=(1000 / 4700) * 0=\underline{0}\) \\
AGi6(cell_4) & \(=(1000 / 4700) * 0=\underline{0}\)
\end{tabular}

The monthly growing areas (in ha) and the area harvested ( AH , in ha \(\mathrm{yr}^{-1}\) ) of irrigated crops distributed to the grid cells are as follows after Rice 1, step 6:

\section*{Results for Rice 1 after step 6:}
- The growing area of 'Rice 1 ' ( \(12,000 \mathrm{ha}\) ) was completely distributed to the grid cells at the end of step 6 .
- Therefore we proceed with the next sub-crop 'Rice 2'.

\section*{Rice \(2,2^{\text {nd }}\) of 2 sub-crops, growing area \(\mathbf{7 , 0 0 0}\) ha, months \(\mathbf{8 - 1 1}\) :}

\section*{Rice 2, Step 3:}

Calculation of AEI_free(cell) according to Equation (3.1):
```

AEI_free(cell_1) = 6000 - max (1924.08, 1924.08, 1924.08, 1924.08) = 6000-1924.08=4075.92
AEI_free(cell_2) = 8000-max(4975.92, 4975.92, 4975.92, 4975.92) = 8000-4975.92 = 3024.08
AEI_free(cell_3) = 2000-max(0,0,0,0)=2000-0 =2000
AEI_free(cell_4) = 0-max(0, 0, 0, 0) =0-0 = 0

```

Calculation of AH_free(cell,subcrop) according to Equations (3.2) and (3.3):
\begin{tabular}{ll} 
AH_free(cell_1) & \(=(1 / 2) * 6000-1800=3000-1800=\underline{1200}\) \\
AH_free(cell_2) & \(=(1 / 2) * 12000-4800=6000-4800=\underline{1200}\) \\
AH_free(cell_3) & \(=\underline{0}\) \\
AH_free(cell_4) & \(=(1 / 2) * 2500-0=1250-0=\underline{1250}\)
\end{tabular}
(condition \(\mathrm{ci}_{\mathrm{i}} * \mathrm{AH}(\) cell, crop \()>\) AGi_base(cell,crop) is true) (condition \(\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}(\) cell, crop) \(>\) AGi_base(cell,crop) is true) (condition \(\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}(\) cell, crop) \(>\) AGi_base(cell,crop) i.e. \((0>0)\) is false) (condition \(\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}(\) cell, crop) \(>\) AGi_base(cell,crop) is true)

Calculation of AGi3_to_distribute(entity,subcrop) according to Equation (3.4):
AGi3_to_distribute(entity) \(\quad=7000-6600=\underline{400}\)
Calculation of AGi3_pot(cell,subcrop) according to Equation (3.6):
```

AGi3_pot(cell_1) = min}(4075.92,1200) = 1200
AGi3_pot(cell_2) = min(3024.08,1200)=1200
AGi3_pot(cell_3) = min(2000,0)=0
AGi3_pot(cell_4) = min(0,1250)=\underline{0

```

Calculation of AGi3_pot(entity,subcrop) according to Equation (3.5):
AGi3_pot(entity) \(=1200+1200+0+0=\underline{2400}\)
Calculation of \(f 3\) (entity,subcrop) according to Equation (3.8):
\(f 3\) (entity) \(\quad=\frac{400}{2400}\)

Calculation of AGi3(cell,subcrop) according to Equation (3.7):
\(\begin{array}{ll}\text { AGi3(cell_1) } & =(400 / 2400) * 1200=\underline{200} \\ \text { AGi3(cell_2) } & =(400 / 2400) * 1200=\underline{200} \\ \text { AGi3(cell_3) } & =(400 / 2400) * 0=\underline{0} \\ \text { AGi3(cell_4) } & =(400 / 2400) * 0=\underline{0}\end{array}\)
The monthly growing areas (in ha) and the area harvested ( AH , in ha \(\mathrm{yr}^{-1}\) ) of irrigated crops distributed to the grid cells are as follows after Rice 2, step 3:

\section*{Results for Rice 2 after step 3:}
- The growing area of 'Rice 2' (7,000 ha) was completely distributed to the grid cells at the end of step 3.
- Steps 4-6 are not necessary for 'Rice 2 ', therefore we proceed with next priority crop maize. The sub-crop 'Maize 1' is the next to process, as its harvested area is larger than that of sub-crop 'Maize 2' and for which the area has already been distributed in step 2.

\section*{Maize 1, \(1^{\text {st }}\) of 2 sub-crops, growing area 600 ha, months 3-7:}

\section*{Maize 1, Step 3:}

Calculation of AEI_free(cell) according to Equation (3.1):
```

AEI_free(cell_1) = 6000-max(124.08, 3735.98, 3735.98,3735.98,3735.98) = 6000-3735.98=2264.02
AEI_free(cell_2) = 8000-max(175.92,6564.02, 6564.02, 6564.02, 6564.02) = 8000-6564.02=1453.98
AEI_free(cell_3) = 2000-max(0, 2000, 2000, 2000, 2000) = 2000-2000 = 0
AEI_free(cell_4) = 0-max(0,0,0,0,0) = 0-0=0

```

Calculation of AH_free(cell,subcrop) according to Equations (3.2) and (3.3):
AH_free (cell_1) \(=(1 / 2) * 200-50=100-50=\underline{50} \quad\) (condition ci \({ }_{i} *\) AH (cell, crop) \(>\) AGi_base(cell,crop) is true)
AH_free(cell_2) \(=(1 / 2) * 300-100=150-100=\underline{50}\)
AH_free(cell_3) = \(\underline{0}\)
(condition \(\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}\) (cell, crop) \(>\) AGi_base(cell,crop) is true) \(^{-}\).
(condition \(\mathrm{ci}_{\mathrm{i}}{ }^{*} \mathrm{AH}(\) cell, crop) \(>\) AGi_base(cell,crop) i.e. \((0>0)\) is false)

AH_free \((\) cell_4) \(=(1 / 2) * 200-0=100-0=\underline{100}\)
Calculation of AGi3_to_distribute(entity,subcrop) according to Equation (3.4):
AGi3_to_distribute(entity) \(\quad=600-150=\underline{450}\)
Calculation of AGi3_pot(cell,subcrop) according to Equation (3.6):
\(\begin{array}{ll}\text { AGi3_pot(cell_1) } & =\min (2264.02,50)=\underline{50} \\ \text { AGi3_pot(cell_2) } & =\min (1453.98,50)=\underline{50} \\ \text { AGi3_pot(cell_3) } & =\min (0,0)=\underline{0} \\ \text { AGi3_pot(cell_4) } & =\min (0,200)=\underline{0}\end{array}\)
Calculation of AGi3_pot(entity,subcrop) according to Equation (3.5):
AGi3_pot(entity) \(=50+50+0+0=\underline{100}\)
Calculation of \(f 3\) (entity,subcrop) according to Equation (3.8):
f3(entity) \(\quad=\underline{1} \quad\) (Remark: as AGi3_to_distribute(entity) \(>\) AGi3_pot(entity))

Calculation of AGi3(cell,subcrop) according to Equation (3.7):
```

AGi3(cell_1) = 1 * 50= 50
AGi3(cell_2) = 1 * 50 = 50
AGi3(cell_3) = 1*0=0
AGi3(cell_4) = 1*0=0

```

The monthly growing areas (in ha) and the area harvested ( AH , in ha \(\mathrm{yr}^{-1}\) ) of irrigated crops distributed to the grid cells are as follows after Maize 1, step 3:

Tab. A 10: Monthly growing areas after distribution step 3 of Maize 1
Cell 1:
\begin{tabular}{rrrrrr}
\hline Month & Rice & Oil palm & Others perennial & Maize & Total \\

\section*{Results for Maize 1 after step 3:}
- An area of 250 ha out of the 600 ha total growing area of 'Maize 1' was distributed to the grid cells at the end of step 3 .
- Step 4 is necessary for 'Maize 1.

\section*{Maize 1, Step 4:}

Calculation of AEI_free(cell) according to Equation (4.1):
\begin{tabular}{lll} 
AEI_free(cell_1) & \(=\underline{0}\) & (condition AH_free \(=0\) is false) \\
AEI_free(cell_2) & \(\underline{0}\) & (condition AH_free \(=0\) is false) \\
AEI_free(cell_3) & \(=\underline{0}\) & (condition ACL \((\) cell \()>0\) is false) \\
AEI_free(cell_4) & \(\underline{0}\) & (condition AH_free \(=0\) is false)
\end{tabular}

Calculation of AGi4_to_distribute(entity,subcrop) according to Equation (4.2):
AGi4_to_distribute(entity) \(\quad=600-250=\underline{350}\)
Calculation of AGi4_pot(cell,subcrop) according to Equation (4.4):
\(\begin{array}{ll}\text { AGi4_pot(cell_1) } & =\text { AEI_free }(\text { cell_1) }=\underline{0} \\ \text { AGi4_pot(cell_2) } & =\text { AEI_free(cell_2) }=\underline{0} \\ \text { AGi4_pot(cell_3) } & =\text { AEI_free(cell_3) }=\underline{0} \\ \text { AGi4_pot(cell_4) } & =\text { AEI_free(cell_4) }=\underline{0}\end{array}\)
Calculation of AGi4_pot(entity,subcrop) according to Equation (4.3):
AGi4_pot(entity) \(=0+0+0+0=\underline{0}\)
Calculation of \(f 4\) (entity,subcrop) according to Equation (4.6):
f4(entity) \(\quad=1 \quad\) (Remark: as AGi4_to_distribute(entity) \(>\) AGi4_pot(entity))
Calculation of AGi4(cell,subcrop) according to Equation (4.5):
```

AGi4(cell_1) = 1*0=0
AGi4(cell_2) = 1*0=0
AGi4(cell_3) = 1*0=0
AGi4(cell_4) = 1*0=0

```

\section*{Results for Maize 1 after step 4:}
- No growing area was distributed to 'Maize 1' in step 4. Therefore the monthly growing areas distributed to the grid cells did not change.
- Step 5 is necessary for 'Maize 1 '.

\section*{Maize 1, Step 5:}

Calculation of AEI_free(cell) according to Equation (5.1):
```

AEI_free(cell_1) $=\underline{0}$
AEI_free(cell_2) $=\underline{0}$
AEI_free(cell_3) $=\overline{2} 000-\max (0,2000,2000,2000,2000)=2000-2000=\underline{0}$
AEI_free(cell_4) =

```
(condition \(\mathrm{ACL}(\) cell \()=0\) is false)
(condition \(\mathrm{ACL}(\) cell \()=0\) is false)
(condition ACL (cell) \(=0\) is true)
(condition \(\mathrm{ACL}(\) cell \()=0\) is false)

Calculation of AGi5_to_distribute(entity,subcrop) according to Equation (5.2):
AGi5_to_distribute(entity) \(\quad=600-250=\underline{350}\)
Calculation of AGi5_pot(entity,subcrop) according to Equation (5.3):
AGi5_pot(entity) \(=0+0+0+0=\underline{0}\)
Calculation of \(f 5\) (entity,subcrop) according to Equation (5.5):
f5(entity) \(\quad=1 \quad\) (Remark: as AGi5_to_distribute(entity) \(>\) AGi5_pot(entity))
Calculation of AGi5(cell,subcrop) according to Equation (5.4):
```

AGi5(cell_1) = 1*0=0
AGi5(cell_2) = 1*0=0
AGi5(cell_3) = 1*0=0
AGi5(cell_4) = 1*0=0

```

\section*{Results for Maize 1 after step 5:}
- No growing area was distributed to 'Maize 1' in step 5. Therefore the monthly growing areas distributed to the grid cells did not change.
- Step 6 is necessary for 'Maize \(1^{\prime}\) '.

\section*{Maize 1, Step 6:}

Calculation of AEI_free(cell) according to Equation (3.1):
\[
\begin{array}{ll}
\text { AEI_free(cell_1) } & =6000-\max (174.08,3785.98,3785.98,3785.98,3785.98)=6000-3785.98=\underline{2214.02} \\
\text { AEI_free(cell_2) } & =8000-\max (225.92,6614.02,6614.02,6614.02,6614.02)=8000-6614.02=\underline{1385.98} \\
\text { AEI_free(cell_3) } & =2000-\max (0,2000,2000,2000,2000)=2000-2000=\underline{0} \\
\text { AEI_free(cell_4) } & =0-\max (0,0,0,0,0)=0-0=\underline{0}
\end{array}
\]

Calculation of AGi5_to_distribute(entity,subcrop) according to Equation (6.1):
AGi6_to_distribute(entity) \(\quad=600-250=\underline{350}\)
Calculation of AGi6_pot(entity,subcrop) according to Equation (6.2):
AGi6_pot(entity) \(=2214.02+1385.98+0+0=\underline{3600}\)
Calculation of \(f 5\) (entity,subcrop) according to Equation (6.4):
f6(entity) \(\quad=\frac{350}{3600}\)
Calculation of AGi6(cell,subcrop) according to Equation (6.3):
\(\begin{array}{ll}\text { AGi6(cell_1) } & =(350 / 3600) * 2214.02=\underline{215.25} \\ \text { AGi6(cell_2) } & =(350 / 3600) * 1385.98=\underline{134.75} \\ \text { AGi6(cell_3) } & =(350 / 3600) * 0=\underline{0} \\ \text { AGi6(cell_4) } & =(350 / 3600) * 0=\underline{0}\end{array}\)
The monthly growing areas (in ha) and the area harvested ( AH , in ha \(\mathrm{yr}^{-1}\) ) of irrigated crops distributed to the grid cells are as follows after Maize 1, step 6:

\section*{Results for Maize 1 after step 6:}
- The growing area of 'Maize 1' (600 ha) was completely distributed to the grid cells at the end of step 6.

All monthly growing areas for all sub-crops and 19,900 ha irrigated harvested area are completely distributed to grid cells, thus the distribution procedure is finished.

\section*{Annex B: Characteristics of the entities}

\section*{Annex C: Documentation of sources of tabular detailed crop calendars for irrigated crops, by continent, by country name}

\begin{abstract}
Annex C contains the complete documentation of crop calendars for irrigated crops, sorted in alphabetical order by continent (Africa, Asia, America, Asia, Europe, and Oceania) and by country name, mentioning data sources and sub-national subdivisions, together with a bibliographic reference list.
\end{abstract}

Reference status of the database is 2007-06-12.

\section*{AFRICA}

\section*{Algeria}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest AQUASTAT report on Africa of the United Nations report on Africa (FAO, 2005e) and sums to 569,418 ha. The actually irrigated area, as the new AQUASTAT report cited only figures for 1986, was taken from the FAO crop calendar for irrigated crops (FAO, 2005b) and scaled to apply to the equipped area of 2001, using the ratio of new to old equipped area cited in the older AQUASTAT report (FAO, 1995a). With roughly 140,000 ha harvested area, vegetables are the most important crop, followed by dates ( \(110,000 \mathrm{ha}\) ) for which the total mean harvested area 1998-2002 from the FAOSTAT database (FAO, 2005d) was assumed to be irrigated, largely double the value than cited for 1986 in the AQUASTAT report. Dates and grapes are both cited in (Achtnich, 1980). Permanent cultures are dates, grapes (also assumed to be \(100 \%\) irrigated), citrus, and fruit trees.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, rice, barley, sorghum and sugar beets) cultivation periods without harvested area that were cited in the crop calendar available in the FAO Global Information and Early Warning System (GIEWS) (FAO, 2005c) were used to define the cropping seasons. They fit into the calendar of Morocco. Winter cropping season is from October to April (wheat), for fodder from October to March. Summer cropping season is from May to September (potatoes, vegetables, rapeseed, and tobacco). All crops have a cropping intensity of 1.

\section*{Angola}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e) and sums to \(80,000 \mathrm{ha}\). The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), the AQUASTAT report and the current survey of 2004. In 1996, roughly 35,000 ha were actually irrigated, mainly rice (ca. 7,000 ha twice), vegetables (ca. \(13,000 \mathrm{ha}\) ), sugar cane (ca. 8,000 ha) and fruits (bananas, citrus).

\section*{Cropping seasons:}

The cropping season as given by the FAO crop calendar for irrigated crops (FAO, 2005b) and those for Zambia were used as a basis. For some crops (wheat, maize, millet, sorghum, and potatoes) cropping seasons are cited in the FAO GIEWS crop calendar (FAO, 2005c), which made adaptations necessary: Rice from September to January and from February to June fits with its first season almost into the mentioned FAO GIEWS crop calendar. All crops have a cropping intensity of 1 , besides rice that has a cropping intensity of 2 .

\section*{Benin}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e), and sums to 12,258 ha fully or partially controlled or wetland equipped area in 2000 . The actually irrigated area was taken from the AQUASTAT report: It is only 2,823 ha! The distribution of this area to crops was made using also information of the FAO crop calendar for irrigated crops (FAO, 2005b), mentioning additionally sugar cane, and of the older FAO AQUASTAT report (FAO, 1995a). Rice as cited major crop is assumed to be grown also in notequipped area. In equipped areas, only 636 ha rice are harvested, 563 ha in known area and a rest area to the total area. A further 1,000 ha sugar cane, 1,107 ha irrigated vegetables, 70 ha pineapples and 10 ha potatoes are irrigated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. The calendar is identical to that of neighbouring Togo: Rice is grown in two seasons from January to May (not from November to March like in Nigeria) and from June to October, resulting in a cropping intensity of 2. But potatoes are assumed to be grown from December to April, like sweet potatoes in neighbouring Nigeria and like vegetables. All crops have a cropping intensity of 1 , besides rice that has a cropping intensity of 2 .

\section*{Botswana}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 1,439 ha of fully and partially controlled areas including equipped lowlands. The actually irrigated area for 2002, 620 ha, was taken from the AQUASTAT report and mentions vegetables and citrus. Unfortunately this list does not at all correspond to that of the FAO crop calendar for irrigated crops (FAO, 2005b), which mentions cotton and maize. The latter was considered to be less confident.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. Vegetables and citrus have a cropping intensity of 1.

\section*{Burkina Faso}

\section*{Irrigated area:}

The area equipped for irrigation, 25,000 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken basically from the new AQUASTAT report and the FAO crop calendar for irrigated crops (FAO, 2005b), from the latter the area for fruit trees. Rice ( 9,470 ha harvested), vegetables, sugar cane and fruits are the most important crops on equipped irrigated area with at least 2,000 ha harvested. Only of secondary importance with
harvested areas below 500 ha are maize, cereal "niébé", potatoes, tobacco and other annual cultures. As permanent crops sugarcane and fruits are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Rice is grown in two seasons from June to October and from November to March. Main irrigation is in winter during the dry season, from November to March, also for cereal "niébé". Maize is assumed to be grown in the wet summer season from June to October and to be additionally irrigated. A cropping intensity of 1 is assumed, and a value of 2 for rice.

\section*{Burundi}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 21,430 ha of fully and partially controlled areas including equipped lowlands. The actually irrigated areas around the year 2000 ( 21,000 ha harvested area) were taken from the AQUASTAT report, assisted by figures from the FAO crop calendar for irrigated crops (FAO, 2005b). Maize and sorghum are cited with large irrigated harvested areas of 43,000 ha and \(18,000 \mathrm{ha}\), respectively, in the latter source. As an inclusion of their areas into the own crop calendar would have exceeded the equipped area, the following assumptions took place: (i) These areas were only cultivated in unequipped irrigation areas and thus per definition not included as irrigated crops in this study, or (ii) They ceased to be irrigated crops due to the decrease of market incentive following falling wages and a rising subsistence farming level as cited in the latest AQUASTAT report on Africa (FAO, 2005e) From the rest of the crops, rice is the most important crop with an harvested area of \(17,380 \mathrm{ha}\), followed by sugarcane, vegetables and coffee.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were taken as a basis. For some crops (maize, sorghum, and beans) cropping seasons identical for Burundi and Rwanda are cited in the FAO GIEWS crop calendar (FAO, 2005c). These seasons fit to the seasons of rice that is grown in two cropping seasons from September to January and from February to June. Vegetables are irrigated in three cropping seasons from January to April, May to August, and September to December. All crops have a cropping intensity of 1, besides rice with a value of 2 and vegetables with a value of 3 .

\section*{Cameroon}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 25,654 ha fully or partially controlled or wetland equipped area. The actually irrigated area was taken basically from the same source. As areas of the informal sector were also included and no explicit separation of irrigated and rainfed harvested areas was made in Table 4 of (FAO, 2005e), some adaptations to the original values were necessary. Rice (ca. 20,000 ha harvested area) was assumed to be \(100 \%\) irrigated, with an asymmetric distribution to the
seasons, the largest area (1st cropping season) during the rainy season from June to October. Irrigated area of maize is fit in order not to surpass the area equipped for irrigation during this month, leading to about \(50 \%\) irrigated harvested area. Vegetables (ca. 11,000 ha during first cropping season) are the second largest crop. The cited irrigated area of melons and pineapples was assumed to be occupied by \(50 \%\) of each crop.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Cameroon and the Democratic Republic of the Congo were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005 c ) were used to define the cropping seasons that were in accordance to the seasons of the former source. Rice is grown in two seasons from June to October (wet season) and from November to April (dry season), like specified in the AQUASTAT report (FAO, 2005e), while the original FAO calendar specifies only one season from May to September. Vegetables are irrigated during only one season from December to April, using the larger area of the 2nd cropping season as given in Table 4 of (FAO, 2005e). This procedure leads to a reasonable cropping intensity of nearly 100 \% during the dry season. Maize is grown from June to October, merging the two seasons given in the GIEWS calendar. A cropping intensity of 1 is assumed, besides for rice with a value of 1.25 .

\section*{Cape Verde}

\section*{Irrigated area:}

The area equipped for irrigation is \(3,109.03 \mathrm{ha}\) (1997) as irrigation potential ( 2,780 ha fully or partially controlled equipped area) according to was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e), citing (Ministère de l'agriculture de l'élevage et de la sylviculture, 1997). The actually irrigated area was taken from the FAO AQUASTAT report. Most of it is sugar cane, followed by potatoes, vegetables and bananas. As other crops for 1985, the older AQUASTAT report on Africa (FAO, 1995a) lists also flowers, which were considered to still exist.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for Gambia and Senegal were used as a basis together with climate characteristics cited in the AQUASTAT report (FAO, 2005e). For some crops (maize and pulses) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. It resulted in a slightly changed seasonal pattern: irrigated seasons are either July to November (supplementary irrigation for potatoes and vegetables) or from December to April (fully irrigated flowers). All crops have a cropping intensity of 1.

\section*{Central African Republic}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 135 ha fully or partially controlled or wetland equipped area. The actually irrigated area was taken basically from the older AQUASTAT report on Africa (FAO, 1995a), citing 68.5 ha effectively irrigated area, mentioning like (FAO, 2005e) rice and vegetables. Therefore, 40 ha were attributed to rice and the rest of 28.5 ha to vegetables.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Cameroon were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Rice is grown from May to September, and vegetables from December to April. All crops have a cropping intensity of 1.

\section*{Chad}

\section*{Irrigated area:}

The area equipped for irrigation, 30,273 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken basically from the new AQUASTAT report. According to this source date palm trees were considered not irrigated. Most important is rice (harvested area of 10,000 ha, of which 1,000 ha stems from a double-cropped area of single 500 ha system), followed by maize, sugar cane, millet, wheat, and vegetables ( \(2,000 \mathrm{ha}\) ). As permanent crop only sugarcane is cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Wheat is grown as irrigated crop from January to May, starting 2 months later than in neighbouring Niger and Libya. Rice is grown in only one season from June to October, under supplementary irrigation, neglecting the relatively small double-cropped area of 500 ha cited in the AQUASTAT report (FAO, 2005e). Main irrigation for vegetables and assumedly sweet potatoes is in winter during the dry season, from December to April. All crops have a cropping intensity of 1.

\section*{Comoros}

\section*{Irrigated area:}

The area equipped for irrigation, 130 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area consists of 85 ha of bananas as cited there.

\section*{Cropping seasons:}

Bananas are the only irrigated permanent crop.

\section*{Congo, Democratic Republic of the}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 10,500 ha fully or partially controlled or wetland equipped. The actually irrigated area for 2000 was estimated to be \(6,800 \mathrm{ha}\). The harvested areas according to the FAO crop calendar for irrigated crops (FAO, 2005b) that mentions the main crops sugar cane and rice were scaled to this figure, resulting in roughly 6,000 ha sugar cane and 2,000 ha rice.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of the Democratic Republic of the Congo (and the Republic of Congo) were used as a basis. No FAO GIEWS calendar was available for this country, so the one of the Republic Congo was used. Rice is grown in two seasons from January to April and from May to September with a cropping intensity of 2 . All crops have a cropping intensity of 1 , besides rice with a value of 2 .

\section*{Congo, Republic}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 2,000 ha fully or partially controlled or wetland equipped area. The actually irrigated area ( \(100 \%\) of the equipped area) for 1993 was taken basically from the same source. Most is sugar cane ( \(1,783 \mathrm{ha}\) ) and the rest vegetables.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Congo (and the Democratic Republic of the Congo) were used as a basis. For some crops (maize and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Vegetables are assumed to be grown from December to April, like in Cameroon. All crops have a cropping intensity of 1 .

\section*{Côte d'Ivoire}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 72,750 ha fully or partially controlled or wetland equipped area. The actually irrigated area was taken from the AQUASTAT report, assisted by the FAO crop calendar for irrigated crops (FAO, 2005b). The older AQUASTAT report on Africa (FAO, 1995a) lists basically the same crops and areas: most is sugar cane (ca. 18,000 ha) and seed beds (ca. 12,000 ha), followed by fruit trees and vegetables.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. This calendar is similar to that of Liberia and Guinea, with the following differences: Vegetables are grown from December to April. Rice is grown in two seasons from January to May ( 2 months later) and from June to October, resulting in a cropping intensity of 2 . All crops have a cropping intensity of 1 , besides rice with a value of 2 .

\section*{Djibouti}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). According to this source, the fully equipped area of 1,012 ha (1999) is the total usable agricultural land, of which only 388 ha were actually irrigated in 1999. The actually irrigated areas of 1989 were linearly scaled to this area. Cereals were assumed to be maize as this cereal is cited in the FAOSTAT database with a harvested area of a similar order of magnitude ( 6 ha ). Vegetables have the largest area ( 338 ha ). As permanent crop ( 50 ha ) date palm trees were assumed.

\section*{Cropping seasons:}

The cropping seasons are based on information in the AQUASTAT report that mentions an irrigation season starting not before mid-November and ending mid-May. This is in agreement with the winter season of the FAO crop calendar for irrigated crops (FAO, 2005b) of Eritrea from December to April. This season was applied to maize and vegetables. All crops have a cropping intensity of 1 .

\section*{Egypt}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,422,178 \mathrm{ha}\), was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). Though desert climate is prominent, in the northern coastal region there is up to 200 mm of annual rainfall. Therefore, the currently actually irrigated areas, being the same, was taken from the AQUASTAT report rather than the mean harvested area from FAOSTAT database (FAO, 2005d), as the former source seemed more reliable given the higher value, especially in the case of barley. Fodder (berseem clover, Trifolium alexandrinum) (ca. 1.2 Mha harvested area), wheat ( 1.0 Mha ), maize ( \(830,000 \mathrm{ha}\) ), rice ( \(650,000 \mathrm{ha}\), mostly in Nile delta), vegetables ( \(470,000 \mathrm{ha}\) ), and cotton ( \(300,000 \mathrm{ha}\) ) are the most important crops. Sweet potatoes and other roots and tubers were attributed to the crop class "potatoes". As permanent crops, fruit trees, citrus, and sugar cane (only present in the Nile valley) exist.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. They showed a greater variety in cropping seasons as given in the AQUASTAT report (FAO, 2005e): The cited three cropping seasons "winter" (November to May), "summer" (April/May to October" and "Nili" (July/August to October)": Winter crops were wheat (November to May) and barley, sorghum and assumedly flowers (November to March). The berseem clover winter cropping season from November to April given in (FAO, 2005b) was enlarged until May and separated into two joint seasons of unequal length and thus halved the growing area of this crop. The seasons last from November to February and from March to May and account for either multiple cropping as fodder with cuts every 1-2 months within a cropping season of 3 or 6/7 months or as pasture grazed by tethered cattle as cited in the AQUASTAT report (FAO, 2005e). Vegetables are grown in two cropping seasons from March to May and from June to September. Sweet potatoes and other roots and tubers were assumed to be grown during the same seasons as potatoes (February to June), likewise also sunflower was assumed to be grown during the same seasons as groundnuts (May to September). Sesame is assumed to be grown like "other annual crops" from June to October. Cotton is grown from July to January. All crops have a cropping intensity of 1, besides vegetables and berseem clover with a value of 2 .

\section*{Equatorial Guinea}

No irrigation is present in Equatorial Guinea.

\section*{Eritrea}

\section*{Irrigated area:}

The area equipped for irrigation, 21,590 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). According to this source, only the fully equipped area of 4,100 ha (1993) is usable, whereas the 16,490 ha spate irrigation area only contributes negligibly to the food production. Thus, the areas cited there for cotton (ca. 1,800 ha) and other crops ( \(4,100 \mathrm{ha}\) ) should be the actually irrigated areas for 1993. The latter are distributed among \(3 / 4\) vegetables and \(1 / 4\) fruits, assumed to be fruit trees. Vegetables have the largest area. The areas cited in the FAO crop calendar for irrigated crops (FAO, 2005b) are assumed to be outdated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Eritrea were used. Vegetables are grown from December to April, cotton from May to November. All crops have a cropping intensity of 1 .

\section*{Ethiopia}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 289,530 ha fully and partially controlled irrigation area. The actually irrigated areas for 2002 were taken from the detailed figures of the AQUASTAT report (FAO, 2005 e ) and the FAO crop calendar for irrigated crops (FAO, 2005b). Other permanent crops besides citrus and bananas are assumed to consist of \(50 \%\) coffee and \(50 \%\) fruit trees. Most important crops are vegetables and maize.

\section*{Cropping seasons:}

The cropping seasons are as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Ethiopia. Cereals are grown in the "Meher" season from June to October. Roots and tubers, pulses and vegetables are grown from November to March. Cotton is grown from April to October. All crops have a cropping intensity of 1 .

\section*{Gabon}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 4,450 ha fully or partially controlled or wetland equipped area. The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), that mentions besides rice ( \(4,450 \mathrm{ha}\) ) about the same area of vegetables ( \(2,000 \mathrm{ha}\) ) and groundnuts \((2,000)\) that are cultivated during the same seasons as rice.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Rice is grown in two seasons, from December to April (like vegetables) and from June to September (like groundnuts). The cropping period of vegetables is the same as in Cameroon. A cropping intensity of 1 is assumed, for rice a value of 2 .

\section*{Gambia}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 2,149 ha fully or partially controlled equipped area reported for the year 1991. The actually irrigated area was taken the FAO crop calendar for irrigated crops (FAO, 2005b) attributing all equipped area to rice cultivation. The new AQUASTAT report did not specify crop areas for these equipped areas. The older AQUASTAT report (FAO, 1995a) lists 11,277 ha of rice, but this includes areas in Mangrove swamps cultivated from August to January as cited in the new report (FAO, 2005e) that are not considered here as irrigated in the narrow sense.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and groundnuts) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. This calendar is mostly identical to that of Senegal, besides that maize is grown shorter. Rice is grown in two seasons from June to October and from November to March, resulting in a cropping intensity of 2. Besides rice, all crops have a cropping intensity of 1 .

\section*{Ghana}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 30,900 ha fully or partially controlled or wetland equipped area reported for the year 2000. The actually irrigated area was taken from the AQUASTAT report: ca. 5,300 ha irrigated rice and assumedly 11,900 ha irrigated vegetables as minimum area in sub-urban Kumasi area. The older AQUASTAT report on Africa (FAO, 1995a) lists rice, vegetables, and maize without a specific area.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Vegetables are assumed to be grown from December to April. Rice is grown in two seasons from January to May (not from November to March) and from June to October, resulting in a cropping intensity of 2. Besides rice, all crops have a cropping intensity of 1 .

\section*{Guinea}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 94,914 ha fully or partially controlled or wetland equipped area reported for the year 2001. The actually irrigated area was taken from the AQUASTAT report, assisted by the FAO crop calendar for irrigated crops (FAO, 2005b). The older AQUASTAT report on Africa (FAO, 1995a) lists rice and vegetables, without a specific area.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. This calendar is similar to that of Gambia, but potatoes, vegetables and other annual cultures are assumed to be grown from June to October rather than from November to March. Rice is grown in two seasons from June to October and from November to March, resulting in a cropping intensity of 2. Besides rice, all crops have a cropping intensity of 1 .

\section*{Guinea-Bissau}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 22,558 ha fully or partially controlled or wetland equipped area in 1996. The actually irrigated area was taken from the AQUASTAT report, as no FAO crop calendar for irrigated crops (FAO, 2005b) existed. The older AQUASTAT report on Africa (FAO, 1995a) lists rice with a much larger area that was assumed to be grown also in non-equipped lowlands and is therefore not considered here. The biggest area is of permanent tree cultures, including citrus (assumed \(100 \%\) irrigated \(1,550 \mathrm{ha}\) ) and bananas, mangoes, pineapples (total of 5,821 ha). Rice (661 ha) and vegetables (530 ha) are only marginally irrigated under equipped area.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Guinea were used as a basis, as none for Guinea-Bissau was available. For some crops (maize, rice, millet, and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Vegetables are assumed to be grown from June to October rather than from November to March. Rice is grown in two seasons from June to October and from November to March, resulting in a cropping intensity of 2 . Besides rice, all crops have a cropping intensity of 1 .

\section*{Kenya}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 103,203 ha fully and partially controlled areas including equipped lowlands. The actually irrigated areas for 2003 were taken from the AQUASTAT report, assisted by figures from the FAO crop calendar for irrigated crops (FAO, 2005b) and the older AQUASTAT
report on Africa (FAO, 1995a) mentioning also values for bananas, citrus, cotton besides the most important crops rice (ca. 14,000 ha), coffee (ca. 13,000 ha) and pineapples.

\section*{Cropping seasons:}

The cropping seasons are as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Kenya. Rice is grown in only one season like maize from April to August during the "long rains" season. Vegetables are assumed to be irrigated in the "short rains" season of the year from October to February, like cotton from September to February. All crops have a cropping intensity of 1.

\section*{Lesotho}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 2,638 ha fully and partially controlled areas including equipped lowlands. The actually irrigated area for \(2002(203 \mathrm{ha})\) was taken from the AQUASTAT report that mentions only vegetables.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of South Africa were used as a basis. Vegetables as the only crop are assumed to be irrigated in the dry season of the year from May to September, with a cropping intensity of 1.

\section*{Liberia}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 2,100 ha fully or partially controlled or wetland equipped area reported for the year 1987. The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the AQUASTAT report does not mention current values besides rice as a major crop in equipped wetland. But it was not clear whether this status would be the same later on, as the calendar mentions only vegetables instead of rice. The older AQUASTAT report on Africa (FAO, 1995a) lists rice without a specific tabulated area.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. Vegetables as the only crop are grown from December to April, during the dry season, with a cropping intensity of 1 .

\section*{Libya Arab Jamahiriya}

\section*{Irrigated area:}

The area equipped for irrigation (470,000 ha) was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007), which is more than the 400,000 ha given in the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken basically from the new AQUASTAT report, mentioning a probably underestimated actually (monthly) irrigated
area of 316,000 ha. Dates (cited in (Achtnich, 1980)) and also grapes were additionally assumed to be present as irrigated crops. For these, the total mean harvested area 1998-2002 form the FAOSTAT database (FAO, 2005d) was assumed to be irrigated. The sum of the harvested areas was scaled down with a factor of roughly \(70 \%\) to fit to the monthly maximum of 316,000 ha. Fodder is berseem clover (Trifolium alexandrinum). Olive trees have the largest area, followed by fodder, wheat, vegetables and barley, only to a much lesser extent potatoes, pulses, groundnuts and tobacco as annual crops. As permanent crops besides dates and grapes, citrus and fruit trees are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, barley, millet, and potatoes) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. The calendar is similar to that of Tunisia: however, wheat is grown shorter in winter from November to April and barley from December to April. Fodder is grown from November to April. All other annual crops are grown in the earlier "summer" season from February to June. All crops have a cropping intensity of 1.

\section*{Madagascar}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,086,291\) ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b) and the FAOSTAT database (FAO, 2005d). In contrast to South Africa with a similar crop calendar, Madagascar has only a small selection of irrigated crops, with solely dominating rice and some additional sugar cane, cotton ( 17,000 ha each) and vegetables ( \(9,000 \mathrm{ha}\) ). The area of vegetables was taken from the FAO crop calendar for irrigated crops (FAO, 2005b) and scaled with the ratio of the new to the old equipped area cited in the older AQUASTAT report on Africa (FAO, 1995a).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, rice, sorghum, and potatoes) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which confirmed the former seasons, also for sorghum. Most crops are grown in summer: Rice is grown in two seasons with a cropping intensity of 2, from November to March and from April to August. Vegetables are grown from June to October according to the FAO calendar of irrigated crops (FAO, 2005b), while cotton is assumed to be grown from January to August. A permanent crop is sugar cane. All crops have a cropping intensity of 1 , besides rice with a value of 2 .

\section*{Malawi}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 56,390 ha fully and partially controlled areas including equipped lowlands. The actually irrigated areas for 2000 were taken from the AQUASTAT report. It mentions mainly sugarcane, tea, coffee, rice and vegetables. The sum area of rice and vegetables
was distributed to rice and vegetables according to the relative shares given in the older AQUASTAT report on Africa (FAO, 1995a).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Malawi were used as a basis. Rice is grown in two seasons, from November to March and from April to August. Vegetables are assumed to be irrigated in the dry season of the year from May to September, with a cropping intensity of 1 , and 2 for rice.

\section*{Mali}

\section*{Irrigated area:}

The area equipped for irrigation, 235,791 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken basically from the new AQUASTAT report and the FAO crop calendar for irrigated crops (FAO, 2005b). Millet, present according to the latter source as irrigated crop, was assumed to have the same harvested area as sorghum, as indicated there. Groundnuts were assumed to be present with the area listed in the irrigation calendar scaled with the ratio of new 2002 to old 1991 equipped area (roughly 235,000 ha / 191,000 ha). By far the most important crop is rice ( 145,000 ha harvested), followed by millet, sorghum and sugar cane. As permanent crops sugarcane and tea are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rainfed/irrigated rice, millet, sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Wheat is assumed to be grown as in Niger and Libya in winter from November to May. Rice is grown in two seasons from June to October and from November to March. Main irrigation is in winter during the dry season, from November to March. Maize is assumed to be grown in the wet summer season and to be additionally irrigated, whereas groundnuts are cultivated in winter from November to March, in contrast to Niger. Only possibly cotton is outside these seasons (November to May). A cropping intensity of 1 is assumed, and a value of 2 for rice.

\section*{Mauritania}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 45,012 ha fully or partially controlled equipped area. The actually irrigated area was taken basically from the new AQUASTAT report and as indication on crops from the FAO crop calendar for irrigated crops (FAO, 2005b). Permanent crop areas ( \(4,751 \mathrm{ha}\) ) were located in oases, with date palm trees covering the total area and other cultures under palm trees 244 ha . The latter was assumed to be the minimum vegetable area during parts of the year. Unfortunately, this area is obviously not consistent with the cited annual production in oases: cereals ( 4,000 tons) and vegetables ( \(4,000-5,000\) tons). A yield of \(16-32\) ton/ha would be present while for maize and sorghum about 0.6 t /ha yield were specified for irrigated fields! Nevertheless, most of the irrigated area is covered with rice (ca. 17,000 ha harvested), date palm trees being the second most important crop.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rainfed "off-season"/irrigated rice, millet, sorghum, crops in low-lying area, "walo" flood recession crops) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Rice is grown in two seasons from June to October and from November to March. Irrigation is also present in winter during the dry season, from November to March. Maize and sorghum are grown in the wet summer season and to be additionally irrigated, whereas vegetables are cultivated in winter from November to March. Only possibly cotton is outside these seasons (November to May). A cropping intensity of 1 is assumed, and a value of 2 for rice.

\section*{Mauritius}

\section*{Irrigated area:}

The area equipped for irrigation, 21,222 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area for 2002 was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b) of Madagascar and the FAOSTAT database (FAO, 2005d). Dominating crop is sugar cane (19,490 ha), followed by vegetables (758 ha).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Madagascar were used as a basis. For some crops (wheat, maize, rice, sorghum, and potatoes) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited. Vegetables are grown from June to October according to the FAO calendar of irrigated crops (FAO, 2005b). The rest of the crops are grown like in Madagascar in winter from December to April, assumedly also tobacco and flowers. All crops have a cropping intensity of 1.

\section*{Morocco}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,484,160\) ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken from the AQUASTAT report and the FAO crop calendar for irrigated crops (FAO, 2005b). With roughly 370,000 ha harvested area, wheat is the most important crop, followed by fodder, other cereals assumed to be mostly maize, and vegetables. Oil crops were assumed to be sunflower, areas for legumes classified as pulses. Areas of groundnuts and tobacco were directly taken from the FAO crop calendar for irrigated crops (FAO, 2005b) assuming that they have rather a smaller extent than indicated by this figures. Permanent areas besides citrus and bananas were attributed to dates and grapes. The respective harvested areas for the time period 1998-2002 according to the FAOSTAT database (FAO, 2005d) were assumed to be \(100 \%\) irrigated, the rest to fruit tree/berry orchards and olives (ca. 240,000 ha).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, barley, and potatoes) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are used to define the cropping seasons. Winter cropping season is from October to April (wheat; maize), also assumed to be valid for sorghum (and in
principle for millet and rye). Summer cropping season is from May to September, besides for sugar beets (March to September) and cotton (July to January). Sunflowers are assumed to be irrigated in the summer season, also potatoes (also grown in winter as rainfed crop), vegetables and tobacco. Also rice has only a cropping intensity of 1 .

\section*{Mozambique}

\section*{Irrigated area:}

The area equipped for irrigation, \(118,120 \mathrm{ha}\), was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b). The figures of 2001 represent the year-long degradation in infrastructure and the disruption of systems due to flood-induced sedimentation of furrows systems in 2000 and 2001. Therefore, the irrigated area of rice has drastically sunken to a quarter or about 4,000 ha since the values for the year 1993 cited in the older AQUASTAT report on Africa (FAO, 1995a). Only for sugar cane and vegetables, the area remained more or less constant. As permanent crops, small areas of citrus besides annual tobacco are irrigated. The rest of the irrigated area was attributed to maize that had nearly the same areas as in the last surveys.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which confirmed the former season for wheat, but was in contrast to for maize. It was decided to use the GIEWS season, as it was assumed that maize was not longer grown after rice as was obviously assumed before the strong decline of rice areas began. Most crops are grown in summer: Rice is grown in only one season, from November to March, Maize from December to April (like sorghum), and tobacco as well as vegetables are grown from June to October. Permanent crops are sugar cane and citrus. All crops have a cropping intensity of 1.

\section*{Namibia}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 7,572 ha fully and partially controlled areas including equipped lowlands. The actually irrigated area was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b) which contributed fruit trees. The areas of 1991 were scaled with the ratio of new (2002) to old (1992) equipped area, under the assumption that relative areas of crops remained constant. Maize is the most important crop, followed by wheat, then by fruit trees, and fodder (of which \(50 \%\) were attributed to be alfalfa/lucerne and \(50 \%\) to be pasture).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which lead to an adjustment of cropping seasons as compared to those of South Africa: Wheat is grown from June to November (rather than May to November),
assumedly together with other annual crops. Maize is grown from December to May (rather than December to April). Cotton is grown from October to April. Fodder crops alfalfa and pasture (classified as managed grassland) are assumed to be grown permanently rather than from June to November. All crops have a cropping intensity of 1 .

\section*{Niger}

\section*{Irrigated area:}

The area equipped for irrigation, 73,663 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken basically from the new AQUASTAT report and the FAO crop calendar for irrigated crops (FAO, 2005b). Dates were additionally assumed to be present as \(100 \%\) irrigated cultures. For them, the total mean harvested area for the time period 1998-2002 from the FAOSTAT database (FAO, 2005d) was taken. Total area of cereals \((21,500\) ha for 1997) was distributed to wheat ( \(3,000 \mathrm{ha}\) as cited in the FAO crop calendar for irrigated crops (FAO, 2005b)), maize ( 500 ha minimum area assumed) and the rest to rice ( 18,000 ha). The figure for rice fits well into the harvested area of FAOSTAT (ca. 22,000 ha irrigated and rainfed rice). The area of roots and tubers ( 6,800 ha for 1997) was distributed to sweet potatoes (assumed \(100 \%\) irrigated), potatoes ( 200 ha assumed minimum area) and the rest to cassava/manioc (ca. \(60 \%\) irrigated). Industrial cultures were cotton and assumedly sugar cane, for which \(100 \%\) irrigation ratio was assumed, taking mean harvested areas for 1998-2002 (FAO, 2005d). Groundnuts were assumed to be present with the area listed in the irrigation calendar, which was scaled with the ratio of new 2002 to old 1989 equipped area (roughly 74,000 ha / 66,000 ha) and thus had the most important harvested area of \(35,500 \mathrm{ha}\), followed by vegetables \((22,500\) ha) and rice ( \(18,000 \mathrm{ha}\) ). As permanent crops sugarcane and dates are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rainfed rice, millet, sorghum, groundnut, and cowpea) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Wheat is assumed to be grown as in Libya in winter from November to May. Rice is grown in two seasons from June to October and from November to March. Main irrigation is in winter during the dry season, from November to March, also for cassava. Maize is assumed to be grown in the wet summer season, like groundnuts and to be additionally irrigated. Only possibly cotton is outside these seasons (November to May). A cropping intensity of 1 is assumed, and a value of 2 for rice.

\section*{Nigeria}

\section*{Irrigated area:}

The area equipped for irrigation, 293,117 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken basically from the new AQUASTAT report and the FAOSTAT database (FAO, 2005d). The biggest share also cited in the FAO crop calendar for irrigated crops (FAO, 2005b) is for vegetables (tomatoes and onions, ca. 48,000 ha harvested area), followed by wheat, maize, sugar cane ( 19,000 ha each). The next crops following by area is pepper ( \(16,000 \mathrm{ha}\) ), cotton, potatoes, and rice ( \(7,000 \mathrm{ha}\) ). Total area of "other crops" ( 24,000 ha for 1997) was distributed to the crops cited in the source using their mean FAOSTAT harvested area 1998-2002 and their assumed importance: ca. \(50 \%\) or 12,500 ha of cowpeas (which
is the most important crop of the pulses group), ca. \(45 \%\) or 10,000 ha of oil palm, and the rest to citrus, cocoa, and natural rubber ( 500 ha minimum area each assumed)

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) that is similar to that of Niger were used as a basis. For some crops (maize, rainfed/irrigated rice, millet, sorghum, cassava, and yams) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Wheat is assumed to be grown as in Nigeria in winter from November to May, potatoes from December to April, like vegetables. Rice is grown in two seasons from June to October and from November to March. Maize is grown in the summer season like wheat, but only once during the first, second and parts of the third season given in the GIEWS calendar. Only cotton is outside these seasons (November to May). A cropping intensity of 1 is assumed, and for rice 2.

\section*{Réunion}

Reunion in Africa, French Guyana, Guadeloupe, and Martinique in America are all served by statistical sources of France and EUROSTAT. In some respect, their statistical data are interdependent.

\section*{Irrigated area:}

The area equipped for irrigation, 13,000 ha, was cited in a regional profile of AGRESTE (AGRESTE Réunion, 2005). The currently actually irrigated area ( 7,584 ha was taken from the national agricultural census, Table AG 2 in (IFEN, 2005). The areas cited for French overseas territories by the Statistical Office of the European Communities (EUROSTAT, 2005) as a total and for their crop list was scaled to the total cited in the IFEN source (IFEN, 2005). For maize, potatoes, fodder plants, fruits and berry orchards and citrus total sums were given for. As further crops rice, vegetables, and sugar cane were assumed. The cited or assumed areas were distributed to the four overseas departments using the harvested area of the FAOSTAT database (FAO, 2005d), the aforementioned national data sources (AGRESTE, national agricultural census) and further information in (Achtnich, 1980).

\section*{Cropping seasons:}

The cropping seasons as given by the crop calendar for Saint Kitts and Nevis were used, that itself is derived from the FAO crop calendar for irrigated crops (FAO, 2005b) for Trinidad and Tobago. In contrast to French Guyana and Guyana, potatoes are cropped in winter from February to April, vegetables from December to April.

\section*{Rwanda}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 8,500 ha fully and partially controlled areas including equipped lowlands. The actually irrigated areas were taken from the AQUASTAT report text (rice 3,500 ha) and assisted by figures from the FAO crop calendar for irrigated crops (FAO, 2005b) (vegetables 2,000 ha).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. For some crops (maize, sorghum, and beans) cropping seasons identical for Burundi and Rwanda are cited in the FAO GIEWS crop calendar (FAO, 2005c). In contrary to the single cropping season given in the FAO calendar of irrigated crops (FAO, 2005b), a double cropping season for rice on the equipped irrigation area is assumed to exist together with water storage. For other areas such as non-equipped lowlands, only single cropping of rice, in alternation with other crops is assumed. Both types are cited in the AQUASTAT report (FAO, 2005e). The GIEWS calendar seasons fit to the same seasons as in Burundi: Rice is grown in two cropping seasons from September to January and from February to June. Vegetables are irrigated in three cropping seasons from January to April, May to August, and September to December.

\section*{Sao Tome and Principe}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 9,700 ha fully or partially controlled or wetland equipped area. The actually irrigated area was taken from the same source that lists data for 1991: 9,500 ha of cacao and 200 ha of vegetables. The FAOSTAT data on harvested area indicate that with an increase until 2002 in cultivated area of vegetables, potentially a larger area than in 1991 is irrigated. However, with no current information on equipped area as a boundary condition, this remains speculative.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Gabon were used as a basis. For some crops (maize and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Vegetables are thus assumed to be grown from December to April. As permanent crop, cacao is cultivated. All crops have a cropping intensity of 1.

\section*{Senegal}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 119,680 ha fully or partially controlled equipped area. The actually irrigated area was taken basically from the new AQUASTAT report and from the FAO crop calendar for irrigated crops (FAO, 2005b). Some crops were assumed to be present beyond those crops cited in the AQUASTAT report (FAO, 2005e): Permanent crop areas for maize (same as in the older AQUASTAT report on Africa (FAO, 1995a) and fruits were taken from the latter source, for citrus the mean harvested area for the time period 1998-2002 from the FAOSTAT database (FAO, 2005d) was used. Nevertheless, most of the irrigated area is covered with rice (ca. 56,000 ha harvested), vegetables ( \(8,500 \mathrm{ha}\) ) and sugar cane ( \(7,500 \mathrm{ha}\) ) being the next important crops. The values cited for 1997 were not scaled to current equipped area, as this would have surpassed the FAOSTAT harvested area.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and groundnuts) cropping seasons in
the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. The calendar is mostly identical to that of Mauritania located to the north. Rice is grown in two seasons from June to October and from November to March. Irrigation is also present in winter during the dry season, from November to March. Maize and sorghum are grown in the wet summer season and to be additionally irrigated, whereas vegetables are cultivated in winter from November to March. Only possibly cotton is outside these seasons (November to May). A cropping intensity of 1 is assumed, and for rice 2.

\section*{Seychelles}

\section*{Irrigated area:}

The area equipped for irrigation, 260 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area consists of 224 ha (208 ha vegetables, 13 ha flowers, 3 ha pulses) as cited there.

\section*{Cropping seasons:}

Vegetables are assumed to be grown like in Madagascar from June to October, as the dry season of the year starts in May and ends in October according to the AQUASTAT report (FAO, 2005e). Flowers are assumed to be permanent crops, like also permanent nurseries for rainfed annual and permanent crops listed in the AQUASTAT report (FAO, 2005e).

\section*{Sierra Leone}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 29,360 ha fully or partially controlled equipped and lowland area in 1992. The actually irrigated area was taken from the AQUASTAT report, assisted by the FAO crop calendar for irrigated crops (FAO, 2005b). The older AQUASTAT report on Africa (FAO, 1995a) lists rice and vegetables, without a specific area.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. This calendar is similar to that of neighbouring Guinea, but vegetables are assumed to be grown from December to March. Rice is grown in two seasons from June to October and from November to March, resulting in a cropping intensity of 2.

\section*{South Africa}

\section*{Irrigated area:}

The area equipped for irrigation is \(1,498,000\) ha according to the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area ( \(1,664,300 \mathrm{ha}\) ) was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b) and the FAOSTAT database (FAO, 2005d). South Africa has a multitude of irrigated crops, with
dominating fodder and wheat, followed by pulses, vegetables, and maize. Areas of rice, barley, millet and sorghum were attributed according to a sum for cereals other than wheat and maize cited in AQUASTAT report on Africa, taking the mean harvested area of rice for the period 1998-2002 with \(100 \%\) irrigation ratio as a constraint and distributing the rest according to the relationship of the harvested areas, omitting other cereals. Fodder was separated to alfalfa, the mean harvested area assumed to be \(100 \%\) irrigated, and the rest assumed to be clover or other items grouped as mixed grasses in the FAOSTAT database, both classified as managed grassland. The figure for other permanent crops was likewise distributed to grapes (assumed \(100 \%\) irrigated) and the rest attributed to fruits and berry orchards including ca. \(10 \%\) other permanent cultures.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, rice, millet and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which confirmed the former seasons besides for sorghum, for which the irrigation season was prolonged for one month. Most crops are grown in summer, besides wheat and barley (May to November), assumed to be possibly cropped after or before the summer crops. Those are cropped from December to April, with the exception of sorghum (December to May) and cotton (October to April). The fodder is assumed to be cropped throughout the year, clover possibly being harvested before cotton is planted. Roots and tubers crops were assumed to be all grown during summer like groundnuts. Permanent crops are fruit and berry orchards, grapes, sugar cane, citrus, bananas, coffee, tea. All crops have a cropping intensity of 1 .

\section*{Somalia}

\section*{Irrigated area:}

The area equipped for irrigation (200,000 ha) was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 50,000 ha fully and partially controlled areas including equipped lowlands and 150,000 spate/flood irrigation. The actually irrigated areas for 2003 were taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the new AQUASTAT report on Africa (FAO, 2005e) as well as the older one (FAO, 1995a) cite only partly tabulated areas. Most important crop is maize (ca. 120,000-150,000 ha) and sorghum (ca. \(40,000 \mathrm{ha}\) ). Many different crops follow. The data base is extremely poor, as no FAOSTAT data is available to check the figures.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for Somalia were used. Most crops including maize and rice are grown during the "Gu" rainy season from April to August. Only sweet potatoes and vegetables are grown in the "Der" season from October to February. Cotton is grown from April to October.

\section*{Sudan}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,863,000\) ha was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken from mainly the AQUASTAT report which cites cropped areas for fully and partially controlled irrigation area and thus misses about 10
\% of the equipped area. From the FAO crop calendar for irrigated crops (FAO, 2005b), only the areas of pulses ( \(46,000 \mathrm{ha}\) ) and citrus (ca. \(12,000 \mathrm{ha}\), about \(100 \%\) of the harvested area from the FAOSTAT database (FAO, 2005d)) were considered to be potentially also irrigated. The cited area of 95,000 ha of irrigated is about five times as large as the cited FAOSTAT harvested area and was considered to be not reliable enough. Only about 800,000 ha or roughly \(43 \%\) of the equipped area are cited to be actually used, due to deterioration of irrigation and drainage infrastructure. This is found in the present compilation with roughly 840,000 ha as maximum monthly irrigated area and \(45 \%\) of the equipped area. In contrast to the former AQUASTAT report from 1995 (FAO, 1995a), cotton dropped from 324,240 ha to roughly half of the area ( \(166,900 \mathrm{ha}\) ), so that sorghum took position no. 1 with roughly 355,000 ha harvested area, both followed by wheat, groundnuts, vegetables, sugar cane, and maize. Pulses and citrus and fruit trees were cited in the crop calendar for irrigated crops, so that they were put with the cited areas in the crop calendars. Permanent fodder (classified as managed grassland) was assumed to be alfalfa, although it is not specified as such in the FAOSTAT database of harvested area (FAO, 2005d).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, millet and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, leading to a similar cropping season than in Egypt but ending two months earlier for winter wheat (November to March), assumed to be the standard winter cropping season. The irrigated season for maize was confirmed also for sorghum (June to October) in the FAO GIEWS crop calendar (FAO, 2005c) and was taken as the standard cropping season for summer. Roots and tubers crops were assumed to be all grown during winter like groundnuts and potatoes. Cotton is grown from April to October. Also rice has only a cropping intensity of 1 .

\section*{Swaziland}

\section*{Irrigated area:}

The area equipped for irrigation is 49,843 ha according to sub-national statistics of (Riddell and Manyatsi, 2003). The actually irrigated area ( \(45,482 \mathrm{ha}\) ) was taken from the latest AQUASTAT report on Africa (FAO, 2005e), assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b) and the FAOSTAT database (FAO, 2005d). Swaziland has known as only main crop sugar cane, whereas in 1994 it had also other crops: 7,000 ha pineapples, 400 ha citrus and 4,400 ha other crops as cited in the older AQUASTAT report on Africa (FAO, 1995a). In the FAO crop calendar for irrigated crops (FAO, 2005b) 22,000 ha cotton are cited that are in principle in accordance with roughly the same figure of the harvested area given in FAOSTAT database (FAO, 2005d), but these do not fit to the new figures given in 2003 for the equipped area. So it may be concluded that cotton is grown under rainfed conditions. Besides the 41,516 ha of sugar cane only the 2,513 ha of citrus are bigger areas. All the other crops (vegetables, maize, rice, potatoes, and bananas) have only marginal areas.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, rice, and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which confirmed the former seasons and the identical ones of surrounding South Africa. All irrigated crops are grown in summer. All crops have a cropping intensity of 1 .

\section*{Tanzania}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 184,330 ha fully and partially controlled areas including equipped lowlands. The actually irrigated areas for 2002 were taken from the AQUASTAT report: mainly rice, maize and a sum for vegetables/beans, bananas and cotton. The latter three shares were distributed arbitrarily from harvested area (mean 1998-2002) from the FAOSTAT database (FAO, 2005d).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) of Tanzania were used as a basis. Rice is grown in only one season, from November to March, maize from April to August. Vegetables are assumed to be irrigated in the dry season of the year from June to October, with a cropping intensity of 1. Cotton is assumed to be grown as in Kenya

\section*{Togo}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 7,300 ha fully or partially controlled or wetland equipped area in 1996. The actually irrigated area was taken from the AQUASTAT report: ca. 514 ha irrigated rice, 933 ha sugar cane and assumedly 840 ha irrigated vegetables as minimum area and 470 ha fruit trees. The older AQUASTAT report on Africa (FAO, 1995a) lists sugar cane, rice, vegetables, fruits and others.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (maize, rice, millet, sorghum, and cassava) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons that were in accordance to the seasons of the former source. Vegetables are assumed to be grown from December to April. Rice is grown in two seasons from January to May (not from November to March) and from June to October, resulting in a cropping intensity of 2.

\section*{Tunisia}

\section*{Irrigated area:}

The area equipped for irrigation, 394,063 ha, was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007), a little bit more than in the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken from the new AQUASTAT report with one exception. For tobacco the area of the FAO crop calendar for irrigated crops (FAO, 2005b) was used and scaled to represent the area in the reference year 2000 with the ratio of new to old equipped area cited in the older AQUASTAT report on Africa (FAO, 1995a). With roughly 92,000 ha harvested area, vegetables are the most important crop, followed by wheat ( \(49,000 \mathrm{ha}\) ). The rest of the cereals area was distributed to sorghum ( \(50 \%\) of harvested area) and the very rest to barley as it is the most important cereal besides wheat and rice is not cultivated. For dates and grapes the total mean harvested area for the time period 1998-2002 from the FAOSTAT database (FAO,

2005d) was assumed to be irrigated, and the rest of permanent crops besides citrus is assumed to be mainly olives (less than \(100 \%\) irrigation ratio) and probably \(100 \%\) irrigated fruit and berry orchards. Citrus, dates and olives are cited as permanent crops in (Achtnich, 1980).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, barley, potatoes and sugar beets) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) were used to define the cropping seasons. This changed the calendar that is similar to the one of Algeria: Wheat is grown longer in winter from October to May (not April) unlike barley and sorghum that are grown from October to April. Sugar beets start earlier - they are grown from January (not February) to July, whereas other summer crops like potatoes, water melons, vegetables, and tobacco are grown from March until July. Fodder is grown from October to March. All crops have a cropping intensity of 1.

\section*{Uganda}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). There are 9,150 ha fully and partially controlled areas including equipped lowlands. The actually irrigated areas for 1998 ( \(2,330 \mathrm{ha}\) ) were taken from the AQUASTAT report, assisted by figures from the FAO crop calendar for irrigated crops (FAO, 2005b). Rice is the most important crop with an area that decreased from 3,580 ha (1987) to 1,650 ha (1998).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for Uganda and Kenya were used. Rice is grown in only one season from April to August, during the same time as the "long rains" season of Kenya. Vegetables are assumed to be irrigated in the "short rains" season of the Kenya from October to February.

\section*{Zambia}

\section*{Irrigated area:}

The area equipped for irrigation is 155,912 ha according to the national development plan (Ministry of Agriculture and Cooperatives, 2002). The actually irrigated area ( \(55,387 \mathrm{ha}\) ) was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b). The figures of 2002 show that sugarcane (ca. 18,000 ha) and wheat (ca. \(12,000 \mathrm{ha}\) ) are the most important crops, followed by rice and vegetables. The area of cotton has strongly declined, probably due to the drought intensive years, as cited in the AQUASTAT report (FAO, 2005e). As permanent crops sugar cane, coffee, bananas, citrus, and small areas of tea are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for Zambia and those for Zimbabwe and South Africa were used as a basis. For some crops (wheat, maize, millet and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which confirmed the former season for wheat. Most crops are grown in summer: Rice is grown like maize in only one season, from December to April, one month later than in Zimbabwe.

In winter wheat, vegetables, and assumedly other annual crops are irrigated. Cotton is grown also in winter from May to November. All crops have a cropping intensity of 1.

\section*{Zimbabwe}

\section*{Irrigated area:}

The area equipped for irrigation, 173,513 ha, was taken from the latest FAO AQUASTAT report on Africa (FAO, 2005e). The actually irrigated area was taken from the AQUASTAT report, assisted by the list in the FAO crop calendar for irrigated crops (FAO, 2005b) and the FAOSTAT. The figures for the year 1999 show that wheat is \(100 \%\) irrigated. Therefore, the mean harvested area from the FAOSTAT database (FAO, 2005d) was taken representing the period 1998-2002 for wheat. For the other cereals, likewise assumed \(100 \%\) irrigated, rice and barley were taken and the rest area was distributed to sorghum. Likewise, the area attributed to vegetables, pulses and potatoes was distributed to potatoes ( \(100 \%\) irrigated harvested area), pulses ( \(10 \%\) irrigated) vegetables (rest of area). Also other annual crop area was distributed to sunflower (10 \% irrigated), flowers ( 40 ha assumed minimum) and groundnuts (rest) potatoes ( \(100 \%\) irrigated harvested area), pulses ( \(10 \%\) irrigated) vegetables (rest of area). For other permanent crops, tree nuts were assumed to be \(10 \%\) irrigated and the rest was distributed to citrus.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as a basis. For some crops (wheat, maize, and sorghum) cropping seasons in the FAO GIEWS crop calendar (FAO, 2005c) are cited, which confirmed the former season for wheat, but like in neighbouring Mozambique was in contrast to that for maize. It was decided to use the GIEWS season. Most crops are grown in summer: Rice is grown in only one season, from November to March, Maize from December to April (like sorghum). Wheat, barley, vegetables and fodder are grown from June to October. Permanent crops are sugar cane, coffee, tea, tree, and citrus. All crops have a cropping intensity of 1 .

\begin{abstract}
AMERICA

\section*{Antigua and Barbuda}

\section*{Irrigated area:}

Area equipped for irrigation, 130 ha , was available for 1996 (FAO, 2000). Based on the AQUASTAT report (FAO, 2000) it was assumed that 120 ha of vegetables and 10 ha of permanent crops assumed to be fruit tress, were cultivated.

\section*{Cropping seasons:}

The cropping seasons of neighbouring Saint Kitts and Nevis (as based on Trinidad and Tobago) were used. In principle, two cultivation periods of annual irrigated crops exist, during summer from June to November and during the dry winter season from December to April (vegetables).
\end{abstract}

\section*{Argentina}

\section*{Irrigated area:}

The area equipped for irrigation, 1.44 Mha , is the one given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). The actually irrigated area was taken from the national agricultural census of the year 2002 (INDEC, 2002). The original data of the 23 mainland provinces and the Federal District (from Jujuy in the North to Tierra del Fuego / Fireland in the South, without territories of Antarctica and the Falkland Islands / Islas Malvinas that are both claimed by Argentina) (Tab. C 1) was given in an inconsistent set of classes, i.e. they were not the same for all provinces. Therefore, when bigger areas were given in aggregated classes they were re-distributed to a final set of classes according to ancillary information on possible crops cited by the agricultural census on one hand, and on the other hand of crops cited in the national atlas of Argentina (Marin, 1986). Especially the tabulated data of the latter on the ordinal number of each province within the national production per crop group was useful for a prioritisation of distribution of harvested area within unspecified areas of the groups "cereals", "oil crops", "horticulture" and "vegetables", industrial crops such as cotton, sugar cane, mate tea and tobacco, "forage crops" such as sorghum and alfalfa, and "others" in a meaningful way. This included sometimes the introduction of new classes that were not listed in the agricultural census. On the other hand, for citrus, fruit trees including olives and sometimes grapes, the level of detail concerning the crops was simplified with a separation of only 4 aggregated classes "citrus", "grapes" (including also areas from a separate class), "fruit trees" and "olive trees".

The final irrigated areas of 2002 are sometimes very different from those given for 1997 in the latest FAO AQUASTAT report (FAO, 2000), especially the much smaller areas cited by the national census for vegetables (ca. 120,000 ha instead of roughly 260,000 ha of horticulture and vegetables), potatoes (ca. 40,000 ha), cotton (ca. \(40,000 \mathrm{ha}\) ), sugarcane (ca. \(80,000 \mathrm{ha}\) ). For fruits trees (ca. 175,000 ha), olives (ca. 30,000 ha), grapes (ca. 190,000 ha), citrus (ca. 25,000 ha) and also for maize (ca. 105,000 ha) and rice (ca. \(115,000 \mathrm{ha}\) ) the values are comparable within some limits. Crops newly identified as irrigated in 2002 include: wheat (ca. 70,000 ha), soybeans (ca. 85,000 ha), tobacco (ca. 35,000 ha), sorghum (ca. \(55,000 \mathrm{ha}\) ) and alfalfa (ca. \(105,000 \mathrm{ha}\) ). The harvested area from the FAOSTAT database (FAO, 2005d) as an upper limit was not reached, same as for the area equipped for irrigation of the 24 entities (Tab. C 1).

To define the cropping seasons, the 23 mainland provinces were grouped to 6 regional agroclimatological zones (Tab. C 2). This was done with own regional expertise and using the climate classification of (Troll and Paffen, 1964) that excellently depicts natural vegetation distribution in South America. This enabled to distinguish the influence of temperate, subtropical and tropical climate, e.g. in terms of number of humid months and mean temperature.

\section*{Cropping seasons:}

As a starting point, the cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used together with the cultivation periods of the FAO GIEWS crop calendar (FAO, 2005c) and of the United States Department of Agriculture (USDA, 1994). Irrigated crops are summer crops that are mainly irrigated from November to April, besides cotton that is grown from October to April. Permanent irrigated cultures are sugarcane, citrus and fruit trees including olives, grapes, tea/mate tea, and alfalfa for forage (Tab. C 3).

\section*{Tab. C 3: Scheme for irrigated cultivation seasons of Argentina}

\end{tabular}

\section*{Barbados}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,000 \mathrm{ha}\), is the one given for 1989 in (FAO, 2000). The actually irrigated area was interpreted from the AQUASTAT report (FAO, 2000) as being the equipped area which was distributed to the cited crops vegetables \((90 \%)\) and fruit trees \((10 \%)\). Vegetables are by far the important irrigated crop.

\section*{Cropping seasons:}

The cropping seasons of neighbouring Trinidad and Tobago were used. In principle, two cultivation periods of annual irrigated crops exist, during summer from June to November and during the dry winter season from December to April (vegetables).

\section*{Belize}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,000 \mathrm{ha}\), is the one given in (FAO, 2000) for 1997. The actually irrigated area was estimated using the crop list in the aforementioned AQUASTAT report (rice, maize, sugarcane, bananas, and citrus) and distributing the total equipped area to the crop with relative shares as in Honduras. Thus, maize, rice, sugarcane are followed by bananas and citrus.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for Honduras were used. Two cropping seasons of annual irrigated crops exist like in also neighbouring Guatemala: For maize and other crops from April to August (maize, rice) and from September to January (maize).

\section*{Bolivia}

\section*{Irrigated area:}

The area equipped for irrigation, \(128,240 \mathrm{ha}\), is the one given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007), the AQUASTAT report (FAO, 2000) citing a slightly smaller value of ( \(128,239 \mathrm{ha}\) ). The irrigated harvested area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as in the former source no harvested crop areas were specified. Potatoes ( \(40,000 \mathrm{ha}\) ), vegetables ( \(30,000 \mathrm{ha}\) ), maize ( \(26,000 \mathrm{ha}\) ) and rice ( \(10,000 \mathrm{ha}\) ) are the most dominant crops. As permanent crops sugarcane, citrus and fruit trees are cultivated with smaller areas of 5,000 ha and less.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Only one cropping season during summer from December to April is present for rice, maize, barley, potatoes, other roots crops and vegetables. The seasons of the FAO GIEWS crop calendar (FAO, 2005c) were in agreement with that of these summer crops, when a broad envelope was defined around the cropping season lasting from December to February/March that was covered by most of the crops with the exception of sweet potatoes that are also sometimes cultivated until May.

\section*{Brazil}

\section*{Irrigated area:}

Different estimations of area equipped for irrigation for Brazil as a whole and for its states exist. According to the original sources, estimations per state for the following seasons are given in:
2001: (Christofidis, 2002), also cited in the national water resources plan (Secretaria de Recursos Hídricos and (ANA), 2003), lists the increasing values of the Brazilian total from 1950-2001
2003/2004: (Christofidis, 2006)
It seems that these sources overestimate the equipped area at least for 2003/2004, as the total increases steadily since 1996, which might be questioned. Nevertheless, the values cited by FAO in the FAO crop calendar for irrigated crops (FAO, 2005b) and the AQUASTAT report (FAO, 2000) which cites the same values as (Secretaria de Recursos Hídricos and (ANA), 2003) give for 1998 the same value for the area equipped for irrigation, \(2,870,404 \mathrm{ha}\), which is near the 2.656 Mha of the former version 3 of the Global Map of Irrigation Areas. It was decided to take as a reference for the version 4 the regionally detailed values of 2001 ( \(3,149,217 \mathrm{ha}\) ) of (Christofidis, 2002), as they are the newest estimation within the reference period 1998-2002 (Siebert et al., 2007).

Sub-national data of actually irrigated areas on state and municipal level for 1996 are available from the agricultural census 1995/1996. It is the most recently available census data as stated by (Cardille and Foley, 2003). (Helfand and Brunstein, 2000) mentions that this relatively well-funded agricultural census for the first time gathered information of planting and harvesting of crops from the same agricultural year. Field trips were done in August 1996, after the harvesting of many annual crops. Due to many precarious establishments (IBGE, 1997), this should lead to a substantial underestimation of the number of counted establishments. In addition, according to (Helfand and Brunstein, 2000), 1996 was a year with small agricultural economic activity. This should lead to an underestimation of agricultural area and production. But this latter finding is not confirmed by the agricultural statistics of the FAOSTAT database (FAO, 2005d). Furthermore, the census mentions a much higher irrigated area for 1996 (ca. 3.126 Mha ) than the previously mentioned sources for 1998. For the present study, the census was considered to deliver the best available inventory with regionally detailed figures on crop areas. It was used also as a representative estimate for the reference year 2000.

The actually irrigated areas were compiled at the level of states with the constraints that the equipped area of 2001 was not overcome. When the total monthly actually irrigated area of the census (for a given year) was larger than the prescribed equipped area, then the crop areas were scaled down to the equipped area (Tab. C 4).

The crop list of the agricultural census contains 57 items and is much more detailed than the one of the FAO crop calendar for irrigated crops (FAO, 2005b) and that of the AQUASTAT report that mentions for 1996 only rice (ca. \(910,000 \mathrm{ha}\) ) and vegetables ( \(318,420 \mathrm{ha}\) ). In the census, even trees for timber and charcoal production are included. These last two classes were excluded from the compilation for our purposes as being non-agricultural usages, extra-ordinary from the global point of view.

For the group "other cereals" that initially had no sub-division, crops were selected from the harvested area from the FAOSTAT database (FAO, 2005d). As relevant irrigated crops within this marginal group barley, sorghum, oats and buckwheat were identified with mostly sorghum as 100 \% representative irrigated cereals for the regions Centre-west, North and North-east. For the

Southeast \(80 \%\) sorghum, \(10 \%\) oats and \(10 \%\) buckwheat were assumed, for the South \(80 \%\) oats, \(10 \%\) barley, and \(10 \%\) buckwheat. As permanent crops sugarcane, citrus, different fruit trees, grapes, flowers, and managed grassland are cultivated. Besides rice (ca. 1 Mha, from the national compilation), sugar cane ( \(525,000 \mathrm{ha}\) ), managed grassland ( \(530,000 \mathrm{ha}\) ), pulses ( \(105,000 \mathrm{ha}\) ), vegetables ( \(210,000 \mathrm{ha}\) ) are most important.

Tab. C 4: Spatial entities of Brazil (states), and their area equipped for irrigation (Unit ha)
\begin{tabular}{clr}
\hline No. & Entity name (states) & Area equipped for irrigation [ha] \\
\hline 1 & Brazil_Acre & 680 \\
2 & Brazil_Alagoas & 156,992 \\

\hline
\end{tabular}

To define the cropping seasons, Brazil with its 27 states or federal units (Tab. C 4) was divided into 6 agro-ecological zones as given in the AQUASTAT report and the agricultural census (Tab. C 5).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were compared to the seasons of the FAO GIEWS crop calendar (FAO, 2005c) and of United States Department of Agriculture (USDA, 1994), in order to be valid for the aforementioned 6 agroecological zones (FAO, 2000). Most irrigated crops are summer crops, prevalently grown in the South, Southeast, the Centre, and the West between November and April, and in the Northeast from January to June, a season also valid for vegetables that are assumed to be irrigated in winter in the North. Winter crops are irrigated from May to October in the first group of zones, and in the North and Northeast from April to October. Cotton is irrigated from October to April in the first group of zones, and from April to October in the North and the Northeast (Tab. C 6).

Tab. C 5: Climate zone grouping of Brazil
\begin{tabular}{|c|c|c|c|}
\hline No. & Zone / region & State name & State number \\
\hline \multirow[t]{4}{*}{1} & South & & \\
\hline & & Paraná & 16 \\
\hline & & Santa Catarina & 24 \\
\hline & & Rio Grande do Sul & 21 \\
\hline \multirow[t]{5}{*}{2} & Southeast & & \\

\(\left.\begin{array}{clccccccc}\hline \text { No. } & \text { Zone / region name } & \begin{array}{c}\text { Winter } \\ \text { crops } \\ \text { Begin }\end{array} & \text { End } & \begin{array}{c}\text { Summer } \\ \text { crops } \\ \text { Begin }\end{array} & \text { End } & \text { Begin } & \text { End } & \text { Remark } \\ \hline 1,2, & \begin{array}{l}\text { South, Southeast, } \\ 3\end{array} & \mathbf{5} & \mathbf{1 0} & 11 & 4 & 10 & 4 & \\ 4,5 & \text { Centre-West } & \text { North, Northeast } & \mathbf{4} & \mathbf{1 0} & 1 & 6 & 4 & 10\end{array} \begin{array}{l}\text { Cotton in winter, Shorter } \\ \text { winter season }\end{array}\right]\)

\section*{Canada}

\section*{Irrigated area:}

The area equipped for irrigation, 785,046 ha, was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). The spatial distribution was made using areas from the national agricultural census of 2001 (Statistics Canada, 2001). Distribution to crops groups forage, cereals, oil seeds and special cultures for the most important provinces Alberta, British Columbia, Manitoba and Saskatchewan (ca. \(90 \%\) of equipped area) were found in (Chinn, 1999). Its relative values were assumed to be representative for Canada and the areas transferred to actually irrigated areas by
assuming that in these provinces \(100 \%\) of the currently used area was irrigated. Thus, by province, this area was multiplied with the percentage of each crop group. Subsequently, the sum of all provinces per crop group was broken down to individual crops by percentages of harvested irrigated area drawn from the Agricultural Census 2002 statistics as means from sum areas for the northwestern zone of the United States of America (states of Washington, Oregon, Idaho, Wyoming, and North Dakota). With the assumption that oil seeds were exclusively represented by sunflower this lead to 17 crops. No scaling to the whole area of Canada was made, so that the national ratio of actually used to equipped areas remained at the \(90 \%\) share of the four provinces on Canada's total. Forage is the most important crop ( \(287,000 \mathrm{ha}\) ), followed by barley, wheat, orchards, sunflowers, vegetables and maize ( \(26,000 \mathrm{ha}\) ).

\section*{Cropping seasons:}

The cropping seasons were assumed to be the same as for neighbouring United States of America. Winter wheat, barley, and rye are assumed to be winter crops grown from October to June (winter wheat) and from November to May (barley and rye). Summer cropping season is from April to September, with the exception of sugar beets (March to September) and cotton (March to October). The only difference to the USA is, that for Canada, only one cropping season for vegetables is assumed from April to September. A cropping intensity of 1 is present for all crops.

\section*{Chile}

\section*{Irrigated area:}

The area equipped for irrigation \(1,900,000\) ha is the one given in (FAO, 2000). The actually irrigated area were taken from the AQUASTAT report (FAO, 2000), supported by information in the FAO crop calendar for irrigated crops (FAO, 2005b). The area of the latter for irrigated wheat \((268,000 \mathrm{ha})\) was assumed to be too high for winter wheat, given that less than half the value (ca. \(110,000 \mathrm{ha}\) ) was cited in the AQUASTAT report. This lower value corresponds to around \(1 / 3\) of the harvested area. The original harvested area was scaled with the corresponding ratio of national equipped area of FAO (FAO, 2000) and the equipped area of the Global Map of Irrigation Areas version 4 (Siebert et al., 2007).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Like in Argentina, summer crops are irrigated from November to March, besides cotton that is grown from April to October. Permanent irrigated cultures are fruits, grapes and citrus. The seasons of the FAO GIEWS general crop calendar were in good agreement with the cropping seasons of the irrigated crops (rice and cotton) or the summer season (millet and sorghum).

\section*{Colombia}

\section*{Irrigated area:}

The area equipped for irrigation \(900,000 \mathrm{ha}\), is the one given in (FAO, 2000). The actually irrigated area were taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the AQUASTAT report (FAO, 2000) cited only public sector irrigation and no private sector actually irrigated areas were cited. Rice and sugarcane are by far the most important irrigated crops above 100,000 ha, followed by vegetables. As permanent crops besides sugarcane, plantains (bananas), fruit orchards and citrus are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Only one cropping season of annual irrigated crops exist, from March to June, besides fro cotton (August to February) and fodder (September to January). The seasons of the FAO GIEWS crop calendar (wheat, maize, rice, barley, sorghum and soybeans) (FAO, 2005c) were in good agreement with the irrigated crop calendar.

\section*{Costa Rica}

\section*{Irrigated area:}

The area equipped for irrigation, 103, 083 ha , is the one given in (FAO, 2000) for 1997. The actually irrigated area was taken from the harvested area from the FAOSTAT database (FAO, 2005d), the FAO crop calendar for irrigated crops (FAO, 2005b), and the AQUASTAT report (FAO, 2000). As for rice and bananas and obviously also for sugarcane the areas in the calendar and the AQUASTAT report were taken from same harvested area statistics as FAOSTAT, the mean harvested areas of the period 1998-2002 were used ( \(59,000 \mathrm{ha}, 47,000\) ha and 46,000 ha, respectively). For the other crops, the other values were taken, as the irrigation ratio was assumed to be less than \(100 \%\). As permanent crops besides sugarcane, plantains, bananas, and citrus are cultivated. As the cultivated irrigated area per month was up to 138,096 ha, it was assumed that this would be the current equipped area rather than the previously cited value.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Two cropping seasons of annual irrigated crops exist, from April to August and from September to January. The seasons of the FAO GIEWS crop calendar (maize, rice, sorghum) (FAO, 2005c) were in good agreement with the irrigated crop calendar, only sorghum (and likewise millet) was assumed to be cropped later from October to April.

\section*{Cuba}

\section*{Irrigated area:}

The area equipped for irrigation, \(870,319 \mathrm{ha}\), is the one given in (FAO, 2000).The actually irrigated area were taken from the AQUASTAT report (FAO, 2000), supported by information in the FAO crop calendar for irrigated crops (FAO, 2005b). Sugarcane, rice and potatoes are major crops above \(100,000 \mathrm{ha}\), besides vegetables and tobacco. Permanent crops are sugarcane and citrus.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Only one cropping season of annual irrigated crops exists. Rice, potatoes and tobacco are irrigated from June to September. The seasons of the FAO GIEWS crop calendar (FAO, 2005c) were in good agreement with the main cropping season of rice, but not for potatoes.

\section*{Dominican Republic}

\section*{Irrigated area:}

The area equipped for irrigation 269,710 ha, is the one given in (FAO, 2000) which is only the area of public systems. The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the AQUASTAT report (FAO, 2000) does not cite crop areas. Similar to Cuba, sugarcane and rice are dominant crops above 100,000 ha harvested area, while vegetables and fruit trees only have marginal areas.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. A main cropping season from March to July is present, about 3 months earlier than in Cuba (June to September). Rice is irrigated on the same areas another time from August to December, with a cropping intensity of 2 . The seasons of the FAO GIEWS crop calendar (FAO, 2005c) were in good agreement with the main and secondary cropping season of rice. For maize and sorghum they list three identical cropping seasons, of which the first corresponds roughly to the main cropping season of rice.

\section*{Ecuador}

\section*{Irrigated area:}

The area equipped for irrigation, \(863,370 \mathrm{ha}\), is the one given in (FAO, 2000). The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the AQUASTAT report (FAO, 2000) cited only public sector irrigation and the linear scaling of the harvested areas via the available sum of public and private irrigation sector did not support the same relationships. Rice and maize are by far the most important irrigated crops above 100,000 ha, followed by permanent crops fruits and sugarcane.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Only one cropping season of annual irrigated crops exist, from May to September. The seasons of the FAO GIEWS crop calendar (FAO, 2005c) (wheat, maize, rice and barley) were in bad agreement with the irrigated crop calendar, perhaps of the difficulties of associating rainfed and irrigated cultivation seasons in a inner-tropical climate.

\section*{El Salvador}

\section*{Irrigated area:}

The area equipped for irrigation, 44,993 ha, is the one given in (FAO, 2000) for 1997. The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b). Fodder (ca. 27,000 ha harvested area), sugarcane (ca. \(9,000 \mathrm{ha}\) ), and maize (ca 2,700 ha) are the most important, followed by coffee and citrus.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Like in neighbouring Honduras, two cropping seasons of annual irrigated crops exist, which
start earlier (with the exception of rice) than in neighbouring Guatemala: For rice and other crops from April to August (rice, maize) and from September to January (rice, fodder). The seasons of the FAO GIEWS crop calendar (maize, rice, beans) (FAO, 2005c) were in good agreement with the irrigated crop calendar for the main cropping season of maize and the main (but not the secondary) cropping season of rice, respectively.

\section*{French Guyana}

\section*{Irrigated area:}

The area equipped for irrigation given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) is 2,000 ha. The currently actually irrigated areas for this French overseas department was drawn from data of the French Environmental Agency (IFEN, 2005), summing to 6,007 ha which was taken as the current equipped area. Information of the EUROSTAT regional database on irrigated areas (EUROSTAT, 2005) was used to distribute additionally areas of specific crops with weighted shares using information on existing equipped areas in French Guyana, Guadeloupe, Martinique, and Réunion. The list of crops not cited by EUROSTAT and their shares were estimated based on information in (Achtnich, 1980) and (FAO, 2000). This lead to an actually equipped irrigated area of 6,007 ha. Thus, French Guyana has mostly irrigated rice and sugarcane, with some marginal vegetable and potatoes areas.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for Guyana were used as far as possible. The cropping seasons of the FAO GIEWS crop calendar (FAO, 2005c) (maize, rice, soybeans) corresponds for rice to the irrigated seasons. In contrast to Guyana, only one single cropping season for rice is necessary to fill the irrigated harvested area of rice with the equipped area. Potatoes are cropped in winter from December to April, vegetables from May to September.

\section*{Grenada}

\section*{Irrigated area:}

The area equipped for irrigation, 218.5 ha , is the one given for 1996 in (FAO, 2000). The actually irrigated area was interpreted from the AQUASTAT report (FAO, 2000) as being the equipped area which was distributed to the cited crops vegetables, fruit trees, cut flowers, maize and root crops assumed to be cassava according to their percentage share in irrigated land. Vegetables are by far the important irrigated crop (197 ha of 219 ha ).

\section*{Cropping seasons:}

The cropping seasons of neighbouring Trinidad and Tobago were used. Two cropping seasons of annual irrigated crops exist, during summer from June to November (maize, cassava) and during winter from December to April (Vegetables, cut flowers).

\section*{Guadeloupe}

\section*{Irrigated area:}

The area equipped for irrigation given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) is 2,000 ha. The currently actually irrigated areas for this French overseas department was drawn from data of the French Environmental Agency (IFEN, 2005), summing to 8,146 ha which was taken as the current equipped area. Information of EUROSTAT regional database on irrigated areas (EUROSTAT, 2005) was used to distribute additionally areas of specific crops with weighted shares using information on existing equipped areas in French Guyana, Guadeloupe, Martinique, Réunion. The list of crops not cited by EUROSTAT and their shares were estimated based on information in (Achtnich, 1980) and (FAO, 2000). This lead to an actually equipped irrigated area of 5,697 ha. Thus, Guadeloupe has mostly irrigated sugarcane and fruit and berry orchards, with some marginal vegetable, potatoes, citrus, and banana areas.

\section*{Cropping seasons:}

The cropping seasons as given by the crop calendar for Saint Kitts and Nevis were used, that itself is derived from the FAO crop calendar for irrigated crops (FAO, 2005b) for Trinidad and Tobago. In contrast to French Guyana and Guyana, Potatoes are cropped in winter from February to April, vegetables from December to April.

\section*{Guatemala}

\section*{Irrigated area:}

The area equipped for irrigation, \(129,803 \mathrm{ha}\), is the one given in the AQUASTAT report (FAO, 2000). The irrigated harvested area ( \(129,803 \mathrm{ha}\) ) was taken from the FAO crop calendar for irrigated crops (FAO, 2005b) as in the former source only percentages for 1997 were given which did not have subdivision for cereals and vegetables, sugarcane and pasture. Sugarcane is by far the most dominant crop with roughly 99,000 ha harvested area, followed by rice (ca. 7,000 ha harvested), and equal shares of ca. 5,000 ha of maize and vegetables each (harvested each 10,000 ha) and bananas. For consistency, the original harvested area was scaled with the corresponding ratio of (rounded) equipped area ( \(130,000 \mathrm{ha}\) ) FAO crop calendar for irrigated crops (FAO, 2005b) and the equipped area of the FAO (FAO, 2000) \((129,803 \mathrm{ha})\).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. In summer, crops are irrigated from April to August (rice, maize, vegetables) and partly also from September to January (maize, vegetables). Permanent irrigated cultures are sugarcane, bananas / plantains and citrus. The seasons of the FAO GIEWS crop calendar (FAO, 2005c) were in good agreement with the summer irrigated crops rice, maize (main and second season).

\section*{Guyana}

\section*{Irrigated area:}

The area equipped for irrigation, \(150,134 \mathrm{ha}\), is the one given in (FAO, 2000). The actually irrigated area was taken from the harvested area from the FAOSTAT database (FAO, 2005d) with the following assumptions from the FAO crop calendar for irrigated crops (FAO, 2005b) and the

AQUASTAT report (FAO, 2000): Sugarcane and rice are \(100 \%\) irrigated, vegetables are only irrigated by roughly \(3 / 5\). Like in neighbouring Venezuela and Colombia, rice and sugarcane are by far the most important irrigated crops. No permanent crops besides sugarcane are irrigated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as far as possible. The cropping seasons of the FAO GIEWS crop calendar (FAO, 2005c) (maize, rice, soybeans) correspond only for rice to the irrigated seasons. A second cropping season for rice is arbitrarily introduced from October to February to reconcile the irrigated harvested area of rice with the small equipped area which is for 1991 and is reported to be in bad conditions in (FAO, 2000) and the assumed \(100 \%\) irrigated sugar cane as a constraint, as the area of it fits to the still bigger area of sugar state farms as cited in (FAO, 2000). For Maize, the cropping season of the FAO GIEWS calendar was used. For the other crops, the same repartitioning as in Venezuela was used, with the summer season starting in April with the rainy season in the interior.

\section*{Haiti}

\section*{Irrigated area:}

The area equipped for irrigation, 91,502 ha, is the one of a national survey for 1991 given in (FAO, 2000). The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the AQUASTAT report (FAO, 2000) does not mention crop areas. In contrast to Cuba and the Dominican Republic, sugarcane ( 9,000 ha harvested area) has only position 4 after rice \((41,000 \mathrm{ha})\), vegetables ( \(15,000 \mathrm{ha}\) ), and maize ( \(12,000 \mathrm{ha}\) ). It is followed by citrus, pulses and small areas of fruit trees and cotton ( 1,000 ha each).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. The same two cropping seasons as in the Dominican Republic are present. A main cropping season from March to July is present, about 3 months earlier than in Cuba (June to September). Rice is irrigated on the same areas another time from August to December, with a cropping intensity of 2 . The seasons of the FAO GIEWS crop calendar (FAO, 2005c) were in good agreement with the main and secondary cropping season of rice. For maize the second cropping season is more or less parallel to the main cropping season. Thus, its meaning is unclear and is not further considered. Sorghum is grown during the second cropping season, from August to December, rather than the first as in the Dominican Republic. Cotton is irrigated from August to February.

\section*{Honduras}

\section*{Irrigated area:}

The area equipped for irrigation, \(73,210 \mathrm{ha}\), is the one given in (FAO, 2000) for 1997. The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b). Maize ( 29,000 ha harvested area), pulses, rice, and sugarcane ( \(11,000 \mathrm{ha}\) ) are the most important. As permanent crops besides sugarcane, bananas, citrus and plantains are cultivated. Other annual crops are vegetables and cotton.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Like in neighbouring Nicaragua, two cropping seasons of annual irrigated crops exist, which start earlier (with the exception of rice) than in neighbouring Guatemala: For maize and other crops from April to August (maize, rice, vegetables) and from September to January (maize, pulses). The seasons of the FAO GIEWS crop calendar (wheat, maize, rice, sorghum, potatoes) (FAO, 2005c) were in good agreement with the irrigated crop calendar for the main and second cropping season of maize and main cropping season of rice, respectively. Cotton is grown from September to March.

\section*{Jamaica}

\section*{Irrigated area:}

The area equipped for irrigation, 25,214 ha, is the one for 1997 given in (FAO, 2000). The actually irrigated area was taken from the AQUASTAT report (FAO, 2000), supported by information in the FAO crop calendar for irrigated crops (FAO, 2005b). Pasture in the AQUASTAT report is considered to be correct and cited as fodder in the FAO calendar. Sugarcane is by far the most important crop, followed by bananas, permanent pasture/fodder (assumed managed grassland) and vegetables. Other permanent cultures (berry orchards, papaya, and coffee) are only present with minor areas.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used and extended with information by the seasons of the FAO GIEWS crop calendar (FAO, 2005c) for Cuba. Two cropping seasons of annual irrigated crops exist. Vegetables are irrigated from May to September, starting one month earlier than in Cuba. Other annual cultures are grown from December to March, pasture as managed grassland throughout the year.

\section*{Martinique}

\section*{Irrigated area:}

The area equipped for irrigation given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) is 3,000 ha. The currently actually irrigated areas for this French overseas department was drawn from data of the French Environmental Agency (IFEN, 2005), summing to 6,730 ha which was taken as the current equipped area. Information of the EUROSTAT regional database on irrigated areas (EUROSTAT, 2005) was used to distribute additionally areas of specific crops with weighted shares using information on existing equipped areas in French Guyana, Guadeloupe, Martinique, Réunion. The list of crops not cited by EUROSTAT and their shares were estimated based on information in (Achtnich, 1980) and (FAO, 2000). This lead to an actually equipped irrigated area of 6,730 ha. Thus, Martinique has mostly irrigated sugarcane and fruit and berry orchards, with some marginal vegetable, potatoes, citrus, and banana areas.

\section*{Cropping seasons:}

The cropping seasons as given by the crop calendar for Saint Kitts and Nevis were used, that itself is derived from the FAO crop calendar for irrigated crops (FAO, 2005b) for Trinidad and Tobago. In contrast to French Guyana and Guyana, Potatoes are cropped in winter from February to April, vegetables from December to April.

\section*{Mexico}

\section*{Irrigated area:}

The area equipped for irrigation sums to \(6,435,800\) ha from irrigation units ("unidades de riego") for 1998 and from irrigation districts ("distritos de riego") for 2004 as given by (CNA, 2005). The irrigated harvested area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b) and scaled to \(5,958,094\) ha with the ratio of the areas equipped for irrigation of the year 2004 of the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) to the area of the year 1995 from the AQUASTAT report (FAO, 2000). Maize is the most important irrigated crop (ca. 1.4 Mha), followed by wheat (ca. 635,000 ha) and sorghum (ca. 650,000 ha). The harvested area for fodder crops as given by the FAO crop calendar for irrigated crops (FAO, 2005b) was partitioned according to data of (FAO, 2000) between cereals for fodder and alfalfa for fodder, and the cereals maize, rye and sorghum as given in the FAOSTAT database (FAO, 2005d). The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of national equipped area of FAO and sub-national equipped area of FAO.

\section*{Cropping seasons:}

Main crops are maize (summer season) and sorghum (summer season) that are irrigated like the other summer crops from June to October. Besides the permanent irrigated cultures of sugarcane, citrus and fruit trees, only wheat (November to May) and rye (for fodder) (November to May) are irrigated in winter. Alfalfa for fodder is assumed to be grown as a permanent crop. Oil crops (ca. \(24,000 \mathrm{ha}\) ) are repartitioned between linseed and mustard seed roughly according to their shares of harvested area in 1998-2002 in the FAOSTAT database (FAO, 2005d) and cropped with the same cropping season but greater share for mustard in the summer than for linseed in winter. This fits well into the kernel seasons given by the FAO GIEWS crop calendar (FAO, 2005c). For maize, the second cropping season during winter for the north-west of Mexico is not considered (kernel growing from November to December, sowing starting in September, harvest ending in March). Likewise for sorghum, the second cropping season in winter was not considered, too (season (2)4\(5(6))\). The resulting percentage of monthly irrigation intensity is a rounded \(44 \%\) throughout the year.

\section*{Nicaragua}

\section*{Irrigated area:}

The area equipped for irrigation, 61,365 ha, is the one given in (FAO, 2000) for 1997. The actually irrigated area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b). Sugarcane and rice are by far the most important crops (21,000-22,000 ha harvested area). As permanent crops besides sugarcane, citrus and bananas are cultivated. Other annual crops are maize, pulses, vegetables, and fodder.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Like in neighbouring Costa Rica, two cropping seasons of annual irrigated crops exist, which start in different months: Rice from February to June and from July to November, and for maize and other crops they start from June to October and from November to March. The seasons of the FAO GIEWS crop calendar (maize, rice, sorghum, beans) (FAO, 2005c) were in good agreement with the irrigated crop calendar for the main cropping season. The secondary and third cropping season are joined for maize and rice, and the secondary are omitted for sorghum.

\section*{Panama}

\section*{Irrigated area:}

The area equipped for irrigation, 34,626 ha, is the one given in (FAO, 2000) for 1997. The actually irrigated area was taken from the AQUASTAT report (FAO, 2000) and the FAO crop calendar for irrigated crops (FAO, 2005b). Sugarcane ( \(15,000 \mathrm{ha}\) ), bananas \((6,000 \mathrm{ha})\) and fruit trees are the most important crops. As permanent crops besides sugarcane, bananas, fruit trees, also plantains are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. In contrast to Costa Rica, only one cropping season of annual irrigated crops exists from May to September starting a month later than in Costa Rica. The seasons of the FAO GIEWS crop calendar (maize, rice) (FAO, 2005c) were in good agreement with the irrigated crop calendar.

\section*{Peru}

\section*{Irrigated area:}

The area equipped for irrigation on province level for 1994 is 1,729,068 ha (Instituto Nacional de Estadística e Informática, 1996), the one given in (FAO, 2000). The actually irrigated area for 1994 is \(1,109,000\) ha (Ministerio de Agricultura, 2006). This area is a little bit less than the value in the FAO crop calendar for irrigated crops (FAO, 2005b). Rice, maize, vegetables, wheat and potatoes are major crops above 100,000 ha. Permanent crops are sugarcane, plantains, fruits and citrus.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Two seasons exist: Cereals in late summer from February, and other annual crops during winter from June to November. Cotton is grown from November to May. The seasons of the FAO GIEWS general crop calendar were in good agreement with the cropping seasons of the irrigated crops.

\section*{Paraguay}

\section*{Irrigated area:}

The area equipped for irrigation, \(67,000 \mathrm{ha}\), is the one given in the AQUASTAT report (FAO, 2000). The irrigated harvested area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as in the AQUASTAT report no harvested crop areas were specified. Sugarcane ( 34,000 ha) and rice \((18,000 \mathrm{ha})\) are the most dominant crops. Vegetables only have marginal areas \((2,000\) ha harvested area).

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. In summer, crops are irrigated from November to March, as in Argentina (rice, vegetables). Permanent irrigated culture is sugarcane. The seasons of the FAO GIEWS crop calendar (FAO, 2005 c ) were in good agreement with the summer irrigated crops rice and vegetables.

\section*{Puerto Rico}

\section*{Irrigated area:}

The area equipped for irrigation, 37,079 ha, is the one given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). The actually irrigated area ( 44,439 cuerdas or 17,465 ha) for 2002 was taken from the USDA Agricultural Census 2002 (USDA and NASS, 2004b), the areas in cuerdas converted into hectares according to the conversion factor of \(0.3,930\) hectare per cuerda specified there. The irrigated crop areas were taken from the list specified there in Table 75. The area missing to the total irrigated area ( 100 ha ) was attributed equally to the 3 classes sugarcane, root crops/tubers, and general primarily livestock farms (classified as managed grassland). As no specific list of irrigated crops existed, the shares of markets values were taken as an indicator of value and probability of irrigation intensity. According to market values, the following sequence was generated: horticultural specialities: \(80 \%\) cultivated area is irrigated, coffee and vegetables/melons: \(40 \%\), citrus (oranges), fruit trees, plantains and bananas: \(30 \%\). This resulted in the sequence of irrigated areas of coffee, plantains \& bananas, vegetables and horticultural specialities..

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) for the Dominican Republic were used. A main cropping season from March to July is present for annual crops, about 3 months earlier than in Cuba (June to September).

\section*{Saint Kitts and Nevis}

\section*{Irrigated area:}

The area equipped for irrigation, 18 ha , is the one given for assumedly 1996 in (FAO, 2000). The actually irrigated area was interpreted from the AQUASTAT report (FAO, 2000) as being the equipped area which was attributed arbitrarily to be \(100 \%\) vegetables.

\section*{Cropping seasons:}

The cropping seasons of near-by Trinidad and Tobago were used as a starting point. In principle, two cropping seasons of annual irrigated crops exist, during summer from June to November and during the dry winter season from December to April (vegetables).

\section*{Saint Lucia}

\section*{Irrigated area:}

The area equipped for irrigation, 297 ha, is the one given for assumedly 1996 in (FAO, 2000). The actually irrigated area was interpreted from the AQUASTAT report (FAO, 2000) as being the equipped area which was distributed to the cited crops pastures ( 65 ha ), bananas ( \(70 \%\) of rest), vegetables ( \(20 \%\) of rest) and fruit trees ( \(10 \%\) of rest). Bananas have by far the largest area.

\section*{Cropping seasons:}

The cropping seasons of neighbouring Trinidad and Tobago were used. In principle, two cropping seasons of annual irrigated crops exist, during summer from June to November and during the dry winter season from December to April (vegetables).

\section*{Saint Vincent and the Grenadines}

According to the AQUASTAT report (FAO, 2000), there is no irrigation in Saint Vincent and the Grenadines.

\section*{Suriname}

\section*{Irrigated area:}

The area equipped for irrigation, \(51,180 \mathrm{ha}\), is the one given for 1998 in (FAO, 2000). The actually irrigated area was taken from the AQUASTAT report (FAO, 2000). Rice ( \(49,000 \mathrm{ha}\) ) and bananas seem nearly \(100 \%\) irrigated and fill the equipped area by \(100 \%\). No permanent crops besides bananas are irrigated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used as far as possible. The cropping seasons of the FAO GIEWS crop calendar (FAO, 2005c) (maize, rice, soybeans) correpond for rice to the single irrigated season from May to September.

\section*{Trinidad and Tobago}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,600 \mathrm{ha}\), is the one given in (FAO, 2000). The actually irrigated area was interpreted from the AQUASTAT report (FAO, 2000) as being the equipped area which was distributed to the cited crops sugarcane, rice and vegetables according to their relationship of harvested area from the FAOSTAT database. Sugarcane is by far the most important irrigated crop.

\section*{Cropping seasons:}

The cropping seasons of Venezuela as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were tried to be used, but the FAO GIEWS general crop calendar showed other main cropping seasons. Two cropping seasons of annual irrigated crops exist, during summer from June to November and during winter from December to April.

\section*{United States of America}

\section*{Irrigated area:}

The area equipped for irrigation, roughly 27.9 Mha, was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). For the sub-national distribution of the irrigated crop areas they were divided into the 51 states or federal districts. Further territories governed by the USA are listed separately, e.g. American Samoa, Guam, etc. (Tab. C 7). The actually irrigated area was taken from the national agricultural census of 2002 (USDA and NASS, 2004a) and (USDA and NASS, 2004e) that cites 41 classes of irrigated crops. The state-level values were aggregated to the national sums, in order to have consistency when sub-national units are considered in downscaling. The values were then converted from unit acres into unit hectares using a conversion factor of 0.40468564224 . On a national scale, the most important crops are forage (ca. 4.16 Mha irrigated harvested area), maize (ca. 4.4 Mha), soybeans (2.2 Mha), cotton (1.9 Mha), rice (1.29 Mha), and
vegetables ( \(954,000 \mathrm{ha}\) ). Permanent cultures are "orchards" (including bearing and non-bearing fruit trees, citrus and vineyards/grapes), berry orchards, and pineapple cultures. For not explicitly cited citrus and grapes, assumptions had to be made according to agro-ecological zones (Tabs. C 8 and C 9). The cultivated area of citrus was assumed to be fully irrigated, including all areas cited for Florida, using information on the states of Arizona, California, Florida, Hawaii, Louisiana, Mississippi, and Texas. The cultivated area of grapes was assumed to be fully irrigated in all states not belonging to the north-eastern, north-western (exception Oregon), and northern Great Plains zone (all besides North and South Dakota). Of course, strong regional differences exist, as the area equipped for irrigation is very different (Tab. C 7).

\section*{Cropping seasons:}

To define the cropping seasons, the USA with its 51 entities (Tab. C 7) were assigned to 7 agroecological zones (Tab. C 8). The overall cropping seasons were synthesised using crop calendars of Europe, information of the normal crop calendar of the United States Department of Agriculture (USDA) - Foreign Agricultural Service (FAS) - Production Estimates and Crop Assessment Division (PECAD) (USDA, 2006), a crop calendar for Oklahoma for 2001-2002 (Oklahoma State University, 2006), for vegetables and fruits in California (DHS, 2006), and for rice according to the International Rice Research Institute (IRRI, 2005).

Irrigated crops were assumed to be mostly cultivated during the summer, normally between May and September or October. Two annual crops have longer seasons: cotton (April to November) and sugar beets (April to September). Winter wheat is the only overall exception, assumed to be grown from October to June, besides in Alaska. A cropping intensity of 1 is assumed, besides for vegetables that are assumed to be grown in two seasons, some times of unequal length, with a cropping intensity of 2 . For specific zones, this standard scheme was adjusted (Tab. C 9)

Tab. C 7: Spatial entities of the USA (states), and their area equipped for irrigation (Unit ha)
\begin{tabular}{|c|c|c|}

\end{tabular}

Tab. C 9: Individual adjustments of crop calendars for irrigated crops in different zones for the United States of America
\begin{tabular}{|c|c|c|c|c|}
\hline No. & Zone name & Remarks on irrigated crops & Citrus irrigated & Grapes irrigated \\
\hline 1 & Northwest & Barley and rye are irrigated. Cotton and vegetables start later than US general. & Not present & Only in Oregon \\
\hline 2 & California & Starting and (often) ending earlier ( -1 month) than in Northwest. Barley and rye are irrigated only in summer. Cotton longer (10+1). Rice longer (9+1) (IRRI calendar) & Yes & Yes \\
\hline 3 & Southwest & Ending later (+1) than Northwest. Barley and rye are irrigated in winter. Cotton longer & Yes (Arizona present) & Yes \\
\hline 4 & Great Plains North & Similar to Northwest. Cotton, sorghum, soybeans ending later. Oats start early (as cited in Oklahoma calendar) & not present & Not in North \& South Dakota \\
\hline 5 & \begin{tabular}{l}
Great Plains \\
South and South
\end{tabular} & Starting much earlier ( -2 ) / often ending later ( +1 ) than in Northwest. Oats start very early (because cited in Oklahoma calendar). Also irrigation in winter. Vegetables longer & Yes (Florida, Louisiana, Mississippi, Texas present) & Yes \\
\hline 6 & Northeast & Like Northwest & Not present & No \\
\hline 7 & Alaska & Only short summer season (May to August). No winter wheat. Only 1 vegetable cropping season. & Not present & No \\
\hline 8 & Hawaii & Similar to Great Plains South \& South. Vegetables longer. Starting much earlier (-2) / often ending later \((+1)\) than in Northwest. Oats very early. Also irrigation in winter. & Not present & Yes \\
\hline
\end{tabular}

\section*{Uruguay}

\section*{Irrigated area:}

The area equipped for irrigation is 217,593 ha according to the agricultural census 2000 (Ministerio de Ganadería, 2001) while the AQUASTAT report (FAO, 2000) lists 181,200 ha for 1998. The irrigated harvested area for outdoor crops is \(216,979 \mathrm{ha}\), not counting covered horticulture. The sum of the sub-national values by department is only 197,492 ha. The crop group "other cereals and oilcrops" was distributed to be \(10 \%\) wheat, \(10 \%\) soybeans, and \(80 \%\) sunflower. Likewise, outdoor horticulture was distributed to \(30 \%\) potatoes and \(70 \%\) vegetables. Other cultures were assumed to be sugarcane, and pasture to be managed grassland. Rice is by far the most dominant crop with
roughly 175,000 ha harvested area, followed by horticulture, managed grassland, citrus, and other fruit trees.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Summer crops including wheat are irrigated from December to April (rice), only vegetables from January to April. Permanent irrigated cultures are citrus, fruit trees, grapes and sugarcane. The seasons of the FAO GIEWS crop calendar (FAO, 2005c) were in good agreement with the summer irrigated crops (December to April and January to April, respectively), with the exception of wheat that is in GIEWS assumed to be grown as winter wheat.

\section*{Venezuela}

\section*{Irrigated area:}

The area equipped for irrigation, \(570,219 \mathrm{ha}\), is the one given in (FAO, 2000). The actually irrigated area were taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as the AQUASTAT report (FAO, 2000) cited no actually irrigated areas. Like in neighbouring Colombia, rice and sugarcane are by far the most important irrigated crops above around 100,000 ha, followed by maize, fruits, coffee, and vegetables. As permanent crops besides sugarcane, fruits, coffee, bananas/plantains and citrus are cultivated.

\section*{Cropping seasons:}

The cropping seasons as given by the FAO crop calendar for irrigated crops (FAO, 2005b) were used. Two cropping seasons of annual irrigated crops exist, during summer from March to September ( 3 months longer than in Colombia) and during winter from December to April, besides for cotton (October to April) and fodder (September to January). The seasons of the FAO GIEWS crop calendar (maize, rice, sorghum and potatoes) (FAO, 2005c) were in good agreement with the irrigated crop calendar.

\section*{Virgin Islands (United States Virgin Islands)}

\section*{Irrigated area:}

The area equipped for irrigation, 185.54 ha, is the one given in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007), as derived from the 456 acres specified in the USDA Agricultural Census 2002 (USDA and NASS, 2004b). The actually irrigated area ( 456 cuerdas or 185.54 ha) for 2002 was taken from the same source, the areas in cuerdas converted into hectares according to the conversion factor of 0.3930 hectare per cuerda specified there. The irrigated crop areas were taken from the list specified there in Table 9, 10, 11 for fruit orchards and coconuts (ca. 50 ha), vegetables, roots and tubers that are all assumed to be \(100 \%\) irrigated. The rest (ca. 95 ha ) is assumed to be managed grassland.

\section*{Cropping seasons:}

The cropping seasons of Puerto Rico, based on that of the FAO crop calendar for irrigated crops (FAO, 2005b) for the Dominican Republic were used. A main cropping season from March to July is present for annual crops, about 3 months earlier than in Cuba (June to September).

\section*{ASIA \\ Afghanistan}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,199,069 \mathrm{ha}\), was set to the one aggregated from district information for 1993 (Siebert et al., 2005). The original harvested area cited by FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area FAO and (Siebert et al., 2005). In the Statistical Yearbook 2003 (CSO, 2004), areas of the oilseeds sunflower, linseed and sesame are cited like for seed cotton for the period 1992-2002. They are consistent with the values given by FAO, so that they were taken as the new reference values, assuming that \(100 \%\) of these crops are irrigated. For wheat the areas of 1991-1996 and 2000-2003, and areas irrigated ( \(1,067,000 \mathrm{ha}\) ) and rainfed ( \(1,237,000 \mathrm{ha}\) ) for 2003 are given (CSO, 2004). As these areas are not consistent with scaled FAO area (ca. 1.9 Mha), the irrigated share of 2003 was applied to the mean wheat area of 2000-2002 given in the Statistical Yearbook (ca. 860,000 ha). Likewise for paddy rice, the value of the latter source (ca. 130,000 ha) and only half of the scaled FAO area was used.

\section*{Cropping seasons:}

The crop calendar shows some similarities to that of Pakistan.
In the winter season, irrigated wheat is grown from November to May. Similarly, barley is cultivated from December to April, potatoes from December to May. Fodder is assumed to be managed grassland and cultivated throughout the year, and not only from November to April. The oilseeds were cultivated throughout the year according to the FAO irrigated crop calendar. This is distributed arbitrarily to sunflower (May to October) and linseed (November to April). Sesame is grown from July to October. All the other annual crops are grown in summer from May to September, besides cotton from April to October. Throughout the year fruit tree cultures are cultivated. The FAOSTAT database (FAO, 2005d) has no information on production in Afghanistan.

\section*{Armenia}

\section*{Irrigated area:}

The area equipped for irrigation, 286,027 ha, was set to the value for 1993 from a national report (Republic of Armenia, 1993) and cited in (Siebert et al., 2005).

The actually irrigated areas of (FAO, 1997b) were scaled with the ratio of areas equipped for irrigation of (FAO, 1997b) and (Republic of Armenia, 1993).

\section*{Cropping seasons:}

Main season is the summer season from July to October. In the winter season, wheat and assumedly barley are cultivated according to the seasons given for winter wheat by the FAO GIEWS crop calendar (FAO, 2005c) from November to June (May assumed for barley), and for maize from May to October.

\section*{Azerbaijan}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,453,318\) ha, was set to the value for 1995 from (FAO, 1997b) and cited in (Siebert et al., 2005). (World Bank, 2003a) mentions currently \(1,100,000\) ha actually irrigated for 2001, also suggesting strong structural changes, such as cutting the cotton area by half from 1995 until 2001, while doubling vegetable area. The fact that in this source no areas of irrigated crops were specified needed a review of the information, of which the final result is presented here. The original harvested area for 1995 cited on page 74 in table 3 by FAO (FAO, 1997b) was taken as a starting point, even if the sum (ca. 760,000 ha) is much smaller than the cited area for 2001. The figures for harvested area from the FAOSTAT database (FAO, 2005d) for the available time period 1992-1995 were taken as a reference, as indicated by the following fact: The rounded irrigated area of cotton for 1995 corresponds nearly exactly to the harvested area. Therefore, irrigation ratios were adjusted to fit the cited irrigated crop areas of 1995 with the following shares: For rice, cotton, melons and vegetables a ratio of \(100 \%\) was assumed, for the other crops \(65 \%\). To yield the final irrigated areas for 1998-2002, the mean harvested area of FAOSTAT was multiplied with the same assumed irrigation ratios, additionally also grain maize, potatoes and sugar beets were assumed to be \(100 \%\) irrigated. The total sum is much less than the cited 1.1 Mha, but it was assumed to be a more reliable estimation given the use of irrigation ratios.

\section*{Cropping seasons:}

The seasons cited in the FAO GIEWS crop calendar (FAO, 2005b) for winter and spring cereals, potatoes and cotton were applied. Wheat, barley and maize are assumed to be irrigated as summer crops from April to August, also potatoes. Cotton is grown from April to October. Only rye is assumed to be irrigated from November to May. All the other annual crops including millet and sorghum are irrigated from July to October.

\section*{Bahrain}

\section*{Irrigated area:}

The area equipped for irrigation, 4,060 ha, is the value cited for 2000 and 2001 in national statistics (Government of Bahrain, 2004) and (Arab Organization for Agricultural Development Agricultural Information, 2003a) as cited in (Siebert et al., 2005).

All cropped area is irrigated due to desert climatic reasons (FAO, 1997c). The crop areas are taken from the FAOSTAT database as mean harvested areas for the time period 1998-2002 (FAO, 2005d).

\section*{Cropping seasons:}

The seasons are assumed to be the same as for neighbouring Saudi-Arabia with similar climate. As permanent crops dates, citrus, grapes and others (e.g. bananas, nut trees) are cultivated. As annual crops besides vegetables, pulses and potatoes are grown during summer from July to November. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3 . Alfalfa as forage and silage crop is assumed to be grown semipermanently throughout the year with 3-4 cuts per year.

\section*{Bangladesh}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,751,045\) ha, was set to the one cited for 1995 by (Bangladesh Bureau of Statistics, 2004) and cited in (Siebert et al., 2005). The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area FAO and (Bangladesh Bureau of Statistics, 2004) as cited in (Siebert et al., 2005), leading to slightly increased values because of an increased number of significant figures.

\section*{Cropping seasons:}

The crop calendar is based on FAO information and is similar to that of eastern India.
Main crop is rice that is irrigated in two cropping seasons throughout the year. The original FAO irrigated crop calendar (FAO, 2005b) that cited a main season in May and June was updated with the information of the FAO GIEWS crop calendar (FAO, 2005c) mentioning three single different cropping seasons for different varieties of rice. So besides the cropping season from December to April, another extended cropping season from May to November is assumed to be present. All the other crops (wheat, potatoes, pulses, vegetables, and rapeseed) are irrigated during winter from December to April, besides the permanently cropped sugarcane.

\section*{Bhutan}

\section*{Irrigated area:}

The area equipped for irrigation, 38,733 ha, is for 1994 as given by (Land Use Planning Project, 1995) in (FAO, 1999) and cited in (Siebert et al., 2005). Rice is the most important crop. The original harvested area cited by FAO was scaled with the corresponding ratio of equipped "wetland" area and (Land Use Planning Project, 1995).

\section*{Cropping seasons:}

Main crop is rice on the terraced valley bottoms being irrigated on roughly 39,000 ha almost only in summer ( 38,734 ha, assumed June to October) and to a much lesser extent in winter ( 545 ha , November to May). The other crops are irrigated in winter from November to May on the same areas as rice. The resulting maximum percentage of monthly irrigation intensity is \(100 \%\) during summer.

\section*{Brunei Darussalam}

\section*{Irrigated area:}

The area equipped for irrigation, 1,000 ha, is the 1995 value of FAO (FAO, 1999) cited in (Siebert et al., 2005). Rice is dominating the crops on ca. 375 ha, but also vegetables (estimated same area as rice) and fruit trees (estimated as rest of equipped area) are cultivated

\section*{Cropping seasons:}

The crop calendar is assumed to be the same as for eastern Malaysia, with only single cropping of rice.

Main crops are rice and vegetables, irrigated only once in summer from May to September. Permanent fruit tree cultures are cultivated.

\section*{Cambodia}

\section*{Irrigated area:}

The area equipped for irrigation, 284,172 ha, is for 2001 as compiled by (Siebert et al., 2005) from data of (Mekong River Commission, 2003) and (FAO, 1994). Rice is the most important irrigated crop, while sugarcane has only relatively small areas. For maize cited in the FAO GIEWS crop calendar (FAO, 2005c), no irrigated area was specified. The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area FAO and the sum given in (Siebert et al., 2005).

\section*{Cropping seasons:}

The crop calendar is very similar to that of Thailand. Like in Lao People's Democratic Republic, the cultivation seasons of rice are different: the second season is longer.

Main crop is rice that is irrigated twice on roughly 165,000 ha from May to September (wet season) and from October to April (dry season). The second season was extended by 2 months, as the crop calendar for 2002 of the FAO GIEWS (FAO, 2005c) gives a longer kernel cultivation seasons. The other culture is permanent sugarcane.

\section*{China}

\section*{Irrigated area:}

China excluding Taiwan has roughly 53.8 Mha area equipped for irrigation. This is the total actually irrigated area in the year 2000 mentioned in the Statistical Yearbook 2001 of China (National Bureau of Statistics, 2001) as cited in (Siebert et al., 2005) and used in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). China was divided into 31 provinces or special autonomous territories with individual area equipped for irrigation (Tab. C 10).

To define the cropping seasons, these 31 entities were grouped into 3 zones or regions (Northeast, Southeast and West) given by the FAO crop calendar for irrigated crops (FAO, 2005b). The assignment of the provinces to these regions was done following notes of (Wang et al., 1999). Some assignment uncertainties exist, as the sum of the areas attributed to the regions according to this source is not fully consistent to the values given for the equipped area in the FAO crop calendar for irrigated crops. The Chongqing province within the Changjiang (Yangtze) basin became independent from the Sichuan province in March 1997 and therefore has no values for 1997 (Wikipedia-Encyclopedia, 2005b). On the other hand, the provinces of Beijing and Tianjin had joint statistics for the area equipped for irrigation. Therefore, both provinces were treated as a new joint entity (Tabs. C 10 and C 11).

Tab. C 10: Spatial entities of China (provinces), and their area equipped for irrigation (Unit ha)
\begin{tabular}{clr}
\hline No. & Entity name (provinces) & Area equipped for irrigation [ha] \\
\hline 1 & China_Anhui & \(3,197,200\) \\
2 & China_Beijing \& Tianjin & 681,400 \\
3 & China_Chongqing & 624,600 \\

\hline & &
\end{tabular}

The basic source of irrigated crop areas was the crop calendar for irrigated crops of FAO. The areas specified there for the group "other cereals" were distributed according to the relative mean harvested areas for the years 1998-2002 in the FAOSTAT database (FAO, 2005d) to barley (ca. \(46 \%\) ), rye (ca. \(22 \%\) ), oats (ca. \(16 \%\) ) and buckwheat (ca. \(16 \%\) ). Oil crops were attributed to other annual crops, as oil palm fruit (with a modelling class of its own) is only a minor product as compared to e.g. linseed and hempseed according to the FAOSTAT database (FAO, 2005d).

The original harvested areas cited in the crop calendar were scaled with the corresponding ratio of equipped area from (Siebert et al., 2007) to (FAO, 2005b). Thus, the irrigated harvested area is 85.6 Mha for China as a whole. The difference between the harvested area and the monthly total of actually irrigated area and the area equipped for irrigation arises from the seasonal intercropping. E.g. in north-eastern China winter wheat is intercropped from October to April, just outside the season of the other annual crops that are cultivated from May to September (Tab. C 12).

Tab. C 11: Actually irrigated areas in China by provinces and FAO regions (years 1997 and 2000) and comparison to areas given in the FAO crop calendar (Unit \(\mathbf{1 , 0 0 0}\) ha, unless otherwise specified)

\section*{Cropping seasons - China North-East and West:}

Irrigated wheat is cropped as winter wheat from October to April, whereas the other annual irrigated crops are cultivated from May to September, besides cotton which is grown from May to November. Sugarcane is grown throughout the year. Permanent fruit and citrus tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer.

\section*{Cropping seasons - China South-East:}

The seasons are quite different from north-eastern China. Irrigated wheat is intercropped as summer wheat from January to May, whereas the other annual irrigated crops are cultivated in two distinct seasons. Cereals are grown in winter from November to March. Other annual crops are grown one month earlier than in north-eastern China, from April to August, besides cotton which is grown from April to October. Sugarcane is grown throughout the year. Permanent fruit and citrus tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer.

\section*{East Timor}

\section*{Irrigated area:}

The area equipped for irrigation ( \(14,000 \mathrm{ha}\) ) was set to the one mentioned for 1990 by (Elshof, 1990) as cited in (Siebert et al., 2005). It was assumed that all irrigation was concentrated in rice, but due to deterioration of irrigation schemes, only \(50 \%\) of the areas were actually irrigated around the year 2000.

\section*{Cropping seasons:}

Crop calendars as for Indonesia outside Java were used, rice being cultivated from December to April.

\section*{Georgia}

\section*{Irrigated area:}

The area equipped for irrigation was set to the value for 2001, 300,000 ha, from a World Bank report (World Bank, 2001) and cited in (Siebert et al., 2005).

The actually irrigated areas given in (FAO, 1997b) were scaled with the ratio of areas equipped for irrigation of (FAO, 1997b) and (World Bank, 2001).

\section*{Cropping seasons:}

Like in neighbouring Armenia, main season is the summer season from July to October. In the winter season, wheat and assumedly barley are cultivated according to the seasons given by the FAO GIEWS crop calendar (FAO, 2005c), from November to June and for barley assumed from November to May, whereas maize is cultivated from May to October.

\section*{Japan}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,129,000 \mathrm{ha}\), is for 1994 from (Ministry of Agriculture, 1994) cited in (FAO, 1999) and cited in (Siebert et al., 2005). The original harvested areas (FAO, 1999) are cited from an AQUASTAT survey questionnaire for Japan (FAO, 1997a). The paddy field area for August 2001 given in (Ministry of Agriculture, 2001) is the sum of field and dyke areas for paddy culture for rice and other cultures. It is considerably higher ( 2.6 Mha ) than the originally harvested area for rice cited by FAO ( 2.2 Mha ), even when only the area of paddy fields without dyke area ( 2.46 Mha ) is looked at. The respective total paddy area on province level is \(2,745,260\) ha (Siebert et al., 2005). The Japan Statistical Yearbook 2006 (Ministry of Internal Affairs and Communications - Statistics Bureau \& Statistical Research and Training Institute, 2006) cites even different national sums: \(2,641,000\) ha for 2000 and \(2,575,000\) ha for 2004. In this source, as planted rice area \(1,665,000\) ha for 2000 and \(1,770,000\) ha for 2003 are cited. The latter figures, together with the original FAO value, correspond to the mean of the harvested rice area in the FAOSTAT database (FAO, 2005d): 2.1 Mha for 1990-1995 and 1.75 Mha for 1998-2002. The necessary conclusion is that currently much less than \(100 \%\) of the equipped area of paddy fields is cultivated, contradicting (Japanese Society of Irrigation, 1995) that says that paddy fields are almost 100 \% irrigated, whereas for non-paddy fields the irrigation rate are said to be just above \(10 \%\). It was suspected that the area classified as paddy fields (either field or dyke areas) in the Yearbook, at best, corresponds only to the equipped area, even if probably nearly \(100 \%\) of rice grown on paddy field is irrigated. Additionally, rice could be grown in upland field areas without irrigation. As no actually irrigated areas were cited in the Yearbook, the 1994 area of the irrigated crops cited by FAO (FAO, 1999) was scaled to the corresponding 2000 areas by the ratio of the mean FAOSTAT harvested areas for the seasons 1990-1995 and 1998-2002. For non-rice crops, the irrigated area of 346,668 ha for 1993 was assumed to be also valid for the time period 1998-2002, and in a first step, the scaled cited areas for wheat, barley, pulses, buckwheat were subtracted. The remainder was then attributed to further crops cited by FAO and (Achtnich, 1980), for which besides for grassland
(arbitrarily fixed \(1,000 \mathrm{ha}\) ) a percentage of the mean harvested area (1998-2002) was assumed to be irrigated. These include fruit tree orchards (ca. 40 \% irrigated), citrus (50 \% irrigated), tobacco (assumed \(100 \%\) irrigated), grassland ( \(1,000 \mathrm{ha}\) ). In a third step, further crops not yet mentioned were assumed to be irrigated, too: sugar cane ( \(100 \%\) irrigated), maize for forage (roughly \(10 \%\) ), potatoes, and sugar beets (roughly \(35 \%\) ). At this stage, all irrigated harvested areas refer still to the originally cited equipped area (year 1993). Subsequently, the harvested areas of all crops were scaled with the corresponding ratio of equipped area FAO and the sum matching prefecture-level of (Ministry of Agriculture, 1994) used for downscaling in (Siebert et al., 2005). This lead to an only marginally increased irrigated harvested area.

Rice is by far the most important irrigated crop besides other crops, although the equipped area is by far not used. This is in agreement with shrinking agricultural production ( \(-10 \%\) up to -30 \%) for nearly all cited crops, as documented in the FAOSTAT database (FAO, 2005d). An exemption is buckwheat, for which the area increased by \(50 \%\).

\section*{Cropping seasons:}

Main crop is rice. According to (Achtnich, 1980) it is irrigated twice in the warmer climate zone of Japan, for which \(1 / 3\) of the harvested area was arbitrarily estimated. The main cropping season is from May to September, in agreement with the FAO GIEWS crop calendar (FAO, 2005c) and the IRRI rice cropping seasons (IRRI, 2005). The second cropping season is assumed to be from October to April. In winter, wheat and barley are potentially irrigated on paddy rice areas from November to May (assuming a late planting of rice) and from November to April, respectively. All the other crops are irrigated during summer from May to September, besides permanent fruit tree orchards, citrus, sugar cane and managed grassland.

\section*{Jordan}

\section*{Irrigated area:}

The area equipped for irrigation, 76,912 ha, was set to the value for 2000 from (Department of Statistics (Jordan), 2004) and cited in (Siebert et al., 2005).

The actually irrigated areas of the irrigated crop calendar for (FAO, 2005b) and of the consistent (FAO, 1997c) were scaled with the ratio of areas equipped for irrigation of (FAO, 1997c) and Department of Statistics (Jordan), 2004 \#252\}.

\section*{Cropping seasons:}

No main season can be determined. Wheat is grown as irrigated crop in winter from September to March, barley possibly on the same areas from April to August. Potatoes are grown from March to July. Vegetables are grown in three seasons of equal length of 4 months starting in January with a cropping intensity of 3 . Oil crops other as olives are assumed to be grown during the same seasons as barley.

\section*{Kazakhstan}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,855,200\) ha, was set to the one aggregated from "oblast" level information for 1993 from (UNDP, 2004) and cited in (Siebert et al., 2005). The fact that different
sources within the same publication (FAO, 1997b) and data for the same years in another publication (World Bank, 1996a) present inconsistent and quite different values of actually irrigated area crop entailed a very detailed review of the information, of which the final result is presented here. The values of (World Bank, 1996a) were considered less reliable. The original harvested area for 1993 cited on page 112 in table 3 by FAO (FAO, 1997b) was taken as a starting point, even if the sum \((2,313,100 \mathrm{ha})\) is much bigger than the area equipped for irrigation. The figures for harvested area from the FAOSTAT database (FAO, 2005d) for the available time period 1992-1995 were taken as a reference, as indicated by the following fact: The rounded irrigated area of cotton corresponds nearly exactly to the harvested area. For cereals, an irrigation ratio of between 20 and \(100 \%\) (maize, rice) was assumed. As fodder crops (cited to be mostly alfalfa), only maize (ca. 1/3, \(20 \%\) irrigation ratio) and grasses plus vegetables/roots for fodder (ca. 2/3, in total only \(7 \%\) irrigation ratio) were assumed to be irrigated, as this way they perfectly fit the cited irrigated area and for these crops figures by FAOSTAT are given. For the moment grasses for fodder are classified as managed grassland and not considered for the modelling. Besides that, other crops could not directly be identified as fodder crops. The originally cited harvested areas were taken, as they are smaller than the harvested areas of FAOSTAT, for the following crops: For wheat, barley (both below \(2 \%\) irrigation ratio). They were fit into the value of 733,200 ha of cereals cited in the tables of (FAO, 1997b), assuming that millet and sorghum were also irrigated (ca. \(30 \%\) irrigation ratio). Also for potatoes (ca. \(30 \%\) irrigation ratio) and oil seeds (ca. \(47 \%\) irrigation ratio) this was done, whereas for sugar beets the mean harvested area was taken, as it was lower than the cited value. The value of 311,700 ha of perennial crops given on page 112 in the table 3 (FAO, 1997b) was assumed to be too high, as fruit trees and berry orchards together with grapes just have roughly 86,000 ha.

\section*{Cropping seasons:}

In the winter season, irrigated wheat and barley are grown from October to May and from December to April, in the southern parts of Kazakhstan according to (World Bank, 1996a), whereas most of them is grown as rainfed cereals in the northern parts, assumedly during summer. Maize (including maize for fodder) is grown from May until October and cotton from May until November, according to the FAO GIEWS crop calendar (FAO, 2005c). The rest of fodder was assumed to be annual cultures to be potentially irrigated all over the year (mixed grasses, vegetables/roots as fodder crops from the FAOSTAT database (FAO, 2005d)).

\section*{Korea, Democratic People's Republic of}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,460,000\) ha, is for 2002, unchanged since 1995 as cited in (Siebert et al., 2005) from FAOSTAT data. Rice is the most important irrigated crop besides vegetables. The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was taken, as no changes in equipped area occured.

\section*{Cropping seasons:}

The crop calendar is similar to that of the Republic of Korea.
Main crop is rice that is irrigated only once on 420,000 ha from May to September, like the other annual cultures as well, besides potatoes that are cultivated from April until September, according to the FAO GIEWS crop calendar (FAO, 2005c). Permanent irrigated culture is fruit trees.

\section*{Korea, Republic of}

\section*{Irrigated area:}

The area equipped for irrigation, \(880,365 \mathrm{ha}\), is for 2002 as compiled by (Siebert et al., 2005) from data of (Ministry of Agriculture and Forestry, 2003). Rice is the most important irrigated crop besides vegetables. The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area of (FAO, 2005b) and the sum given in (Siebert et al., 2005). This lead to a reduced irrigated area, as (Ministry of Agriculture and Forestry, 2003) cites roughly 290,000 ha partially irrigated paddy rice land that is not included in the equipped area which was scaled down to fit province level totals by (Siebert et al., 2005).

\section*{Cropping seasons:}

Main crop is rice that is irrigated only once on roughly 600,000 ha from May to September, like the other annual cultures as well. The permanent cultures are citrus and fruit trees.

\section*{Kuwait}

\section*{Irrigated area:}

The area equipped for irrigation of 6,968 ha was set to the value for 2000 from (Ministry of Planning, 2002) and cited in (Siebert et al., 2005).

All cropped area is irrigated due to desert climatic reasons (FAO, 1997c). The crop areas are taken from the FAOSTAT database as mean harvested areas for the time period 1998-2002 (FAO, 2005d).

\section*{Cropping seasons:}

The seasons are assumed to be the same as for neighbouring Saudi-Arabia with similar climate. Wheat and barley are grown as irrigated crop in winter from December to June and from December to April, respectively. Maize and potatoes are possibly cropped on the same plots as wheat and barley from July to November. Vegetables are grown in only one season from July to November. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3 . Other annual forage crops are assumed to be grown only from December to April, other annual crops from July to November. As permanent crops dates, citrus, and grapes are cultivated.

\section*{Kyrgyzstan}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,075,040 \mathrm{ha}\), was set to the one aggregated from "raion" and "oblast" level information for 1994 from (Asian Development Bank, 1995) and cited in (Siebert et al., 2005). The original harvested area for 1994 cited by FAO (FAO, 1997b) was taken as a starting point, as the sum \((1,076,900 \mathrm{ha})\) is slightly lower than the area equipped for irrigation. The figures for harvested area from the FAOSTAT database (FAO, 2005d) for the available time period 19921995 were taken as a reference, as indicated by the following fact: The rounded irrigated area of cotton corresponds nearly exactly to the harvested area. For most of the crops, an irrigation ratio of \(100 \%\) was assumed. As fodder crops, only maize and grasses plus vegetables/roots for fodder (almost \(100 \%\) irrigation ratio) were assumed to be irrigated, as they perfectly fit the cited irrigated
area and for these crops figures by FAOSTAT are given. For the moment grasses for fodder are classified as managed grassland and not considered for the modelling. Besides that, other crops could not directly be identified as fodder crops. For barley and potatoes, the originally cited harvested areas were taken, as they are smaller than the harvested areas of FAOSTAT ( \(35 \%\) and 20 \% irrigation ratio). Rice is not cited and the FAOSTAT data were used. The FAOSTAT harvested area of other crops was used as it gives assumedly a more realistic estimation for the actually irrigated area, especially when a trend in the time series of the harvested area is present like for wheat and sugar beets, that both increase. Sometimes the FAOSTAT values are higher than the tabulated ones (like for maize). The rest of the value for cereals given in (FAO, 1997b) was assumed to be too high, such as a maximum extent, whereas for vegetables, it was the contrary. The value for perennial crops given in (FAO, 1997b) was assumed to be quite realistic for permanent crops fruit trees and berry orchards, grapes and citrus that were assumed to be irrigated. Other irrigated harvested areas cited by FAO (FAO, 1999) were considered less reliable, besides the mentioning of tobacco as a crop.

\section*{Cropping seasons:}

The crop calendar for Afghanistan was used as a starting point for neighbouring mountainous Tajikistan and Kyrgyzstan.

In the winter season, irrigated wheat is grown from October to May according to the FAO GIEWS crop calendar (FAO, 2005c), one month earlier than in Afghanistan. Similarly, barley is cultivated from December to April. Rice, vegetables and tobacco (not cited for Afghanistan) were assumed to be grown during summer from July to October, maize (including maize for fodder) from May until October according to the FAO GIEWS crop calendar (FAO, 2005c), different to Afghanistan, cotton from May until November. All other fruits are grown from July to October, like potatoes and sugar beets (in Afghanistan from December to May) and sunflower (in Afghanistan from May until October). Perennial fodder was assumed to be mainly fruit and nut trees. The rest of fodder was assumed to be annual cultures to be potentially irrigated all over the year (mixed grasses, other fodder crops from the FAOSTAT database (FAO, 2005d)).

\section*{India}

\section*{Irrigated area:}

India has roughly 57.3 Mha equipped area for irrigation according to the Global Map of Irrigation Areas (Siebert et al., 2007). To distribute irrigated crop areas on a sub-national level, India was divided into 35 states or national territories with different area equipped for irrigation from 1000 ha to 12.5 Mha (Tab. C 13). To define the cropping seasons, these 35 spatial entities were grouped to 4 zones or regions (North, East, South, and West) by the FAO crop calendar for irrigated crops (FAO, 2005b). The distribution of the states to these regions is the mainly the same as that given by the national agronomic statistical institute INDIAAGRISTAT. Some attribution insecurities exist. The new state of Chhatisgarh became independent from the state of Madhya Pradesh in November 2000. The island groups of Andaman / Nicobar and Lakshadweep were both excluded from region "South", but counted as separate regions. Andaman and Nicobar Islands have no irrigation. Lakshadweep Islands have a total of 1,000 ha, but with the crop groups below 500 ha each and no detailed information on crops. Therefore, they were treated as if they had no irrigation.

The basic source of irrigated areas per crop was the time series from 1995/1996 to 2000/2001 from INDIAAGRISTAT, extended by information of the crop calendar for FAO (FAO, 2005b). The area equipped for irrigation was set to the one cited for 2000 by INDIAAGRISTAT. If
no corresponding group could be found, the original harvested areas cited by FAO were scaled with the corresponding ratio of equipped area. For the groups of potatoes, vegetables and fruits, the harvested areas cited in the FAO crop calendar were taken to distribute accordingly the new crop area cited for 2000 for the group of vegetables, fruits and root crops to these three groups. Millet was formed of the tabulated items "other cereals \& millets", "ragi / marua" (with ragi = Eleusine coracana (L.) Gaertn. subsp. Coracana) and "bajira" (i.e. Pennisetum glaucum). Sorghum was formed from the item "jowar" (i.e. Sorghum bicolor (L.) Moench).

For the Lakshadweep Islands INDIAGRISTAT cites less than 500 ha of food crops (pulses, vegetables) and less than 500 ha of non-food crops, summing to a total of roughly 1,000 ha, which is the minimum statistical unit of the dataset. As for other entities such values were not counted also, the actually irrigated area was set to be zero to obtain consistency with sum values for regions and India as a whole.

In the four sub-national regions different crops dominate (Tab. C 14):
- In eastern India: rice (ca. 6.6 Mha harvested in 2 cropping seasons) and wheat (2.3 Mha).
- In northern India: wheat (14.7 Mha, assumed 2 cropping seasons), rice (8.9 Mha, assumed 3 cropping seasons), sugarcane (2.1 Mha), rapeseed (1.1 Mha), cotton (1.3 Mha.
- In southern India: rice (7.3 Mha, 2 seasons), sugar cane (1 Mha), and cotton (330,000 ha).
- In western India: wheat (5.7 Mha) outcomes rice (2.2 Mha, 1 cropping season only), also strong: pulses (1.7 Mha), rapeseed (1.5 Mha) and cotton (1.4 Mha).

\hline & & \\
\hline
\end{tabular}

\section*{Cropping seasons:}

\section*{India East:}

In the eastern region, the harvested area according to the FAO crop calendar and INDIAAGRISTAT were in accordance.

For sunflowers that are not included in the FAO crop calendar, a cropping season like for soybean from June to October was assumed.

\section*{India North:}

In the northern region, in the Ganges basin at the foot of the Himalayan mountain range, the cropping intensity is very high. In order to meet the constraints of the high harvested area and the fixed area equipped for irrigation, for the dominating crops wheat and rice additional cropping seasons to those of the original FAO crop calendar for irrigated crops (FAO, 2005b) were
introduced. This enabled the consistency with the equipped area which would have been extremely exceeded with the standard calendar.

First, instead of two cropping seasons for rice as cited by FAO, a third cropping season was assumed to exist according to the cropping seasons cited in the rice crop calendar for the International Rice Research Institute (IRRI, 2005). There, for the winter season ("kharif") an early and a main cropping season are cited, positioned on the mean from April to July and from August to November, respectively. For the summer season ("rabi"), one cropping season is cited, lasting from December to March. So rice is assumed to be cultivated and irrigated throughout the year.

For wheat, instead of only one cropping season in winter from November to March, a second one during the summer from June to October was introduced. Under the assumption that the winter season is the main irrigated season with less precipitation, an asymmetry between the two cropping seasons. For the winter cropping season the original crop area (for one cropping season) was scaled to current conditions (ca. 8.08 Mha ) with the ratio of the equipped area cited in the crop calendar by FAO and the current one cited by INDIAAGRISTAT. The remainder to the total harvested area was distributed to the summer season.

Soybeans were not cited by INDIAAGRISTAT for the north, so that zero values instead of higher values cited by FAO were assumed to be correct.

For groundnuts and sunflowers that are not included in the FAO crop calendar, a cropping season from June to October like that for soybeans was assumed.

\section*{India South:}

In the southern region, the harvested area according to the FAO crop calendar and INDIAAGRISTAT were in accordance.

No rapeseed is cultivated. For sunflowers that are not included in the FAO crop calendar, a cropping season like for soybeans and groundnuts from July to November was assumed.

\section*{India West:}

The harvested area according to the FAO crop calendar and INDIAAGRISTAT are very different for wheat of which only 6 million hectares instead of 9 million hectares were irrigated. Therefore, the overall cropping intensity is much smaller than with the older data. Wheat is grown in only one cropping season from December to June, two months longer than in the corresponding season of the other regions.

For sunflowers that are not included in the FAO crop calendar, a cropping season like for soybeans and groundnuts from July to November was assumed.

Tab. C 14: Zone grouping of India

\section*{Indonesia}

\section*{Irrigated area:}

The area equipped for irrigation, roughly 4.5 Mha , is the one cited for 1990 by (Elshof, 1990) and found to be consistent with the 1996 values of FAO (FAO, 1999) as cited in (Siebert et al., 2005). The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area of (FAO, 1999) and (Elshof, 1990) as cited by (Siebert et al., 2005). According to (Siebert et al., 2005), the island of Java has a bigger equipped irrigated area than the rest of the Indonesian islands and not the same areas as cited in (FAO, 2005b) (Tab. C 15).

Tab. C 15: Spatial entities of Indonesia (zones), and their area equipped for irrigation (Unit ha)
\begin{tabular}{clr}
\hline No. & Entity name (zone) & Area equipped for irrigation [ha] \\
\hline 1 & Indonesia_Java & \(2,907,000\) \\
2 & Indonesia_Outside Java & \(1,552,000\) \\
\hline
\end{tabular}

\section*{Cropping seasons:}

Crop calendars are separated into the Island of Java and the rest of the countries' islands, but in principle similar to that of neighbouring Thailand. The cropping seasons are in the same, besides that for Java a second cropping season for rice is present.

Main crop is rice that is irrigated from July to November, on the island of Java the bigger area share is irrigated in another cropping season from December to April on a higher area. All the other crops are irrigated also from July to November, besides the permanently cropped sugarcane.

\section*{Iran}

\section*{Irrigated area:}

The area equipped for irrigation \(6,913,800 \mathrm{ha}\), was set to the one cited for 1994 by the Statistical Yearbook 2003 (Statistical Centre of Iran, 2004) and cited in (Siebert et al., 2005). For most crops, the original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area FAO and (Siebert et al., 2005). The FAO value for permanent crops (ca. 1.5 Mha ) was assumed to consist of fruit trees, citrus and dates. The relationship between the statistical yearbook value for orchards and nurseries for 1994 ( \(756,000 \mathrm{ha}\) ) and the FAO value for citrus ( \(153,000 \mathrm{ha}\) ) was taken to distribute the remaining permanent crop area, the permanent crop area minus the area for dates ( 185,000 ha harvested area for 2000 cited in the FAOSTAT database (FAO, 2005d)). The resulting areas for citrus and fruit trees are higher than the values in the statistical yearbook. Nevertheless, they fit into the crop calendar pattern of FAO and the consistent FAO information.

\section*{Cropping seasons:}

The crop calendar shows similarities to that of Pakistan.
In the winter season, irrigated wheat is grown from October to May. Similarly, barley is cultivated from November to March and fodder from November to April. All the other annual crops are grown from May to September, besides cotton from April to October. Throughout the year tree cultures (citrus, fruits, dates) are cultivated. Sugarcane which is cited by (Achtnich, 1980) has zero values in the FAOSTAT database and thus not considered.

\section*{Iraq}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,525,000\) ha, was set to the one cited for 1990 by FAO (FAO, 1997 c ) and cited in (Siebert et al., 2005). For most crops, the original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) were taken directly, as the reference value for
the equipped area is identical. As neither FAOSTAT information nor other sources specified additional crops, the list was considered as exhaustive.

\section*{Cropping seasons:}

The crop calendar shows similarities to that of Iran, but much more spread in terms of cultivation seasons. The kernel cultivation seasons of the FAO GIEWS crop calendar (FAO, 2005c) correspond to the FAO calendar of the irrigated crops.

In the winter season, irrigated wheat is grown from December to June. Similarly, barley is cultivated from December to April and fodder from November to April. All the other annual crops are grown in different seasons: potatoes from February to May, pulses and vegetables from March to July, sunflower and sesame from April to August, besides cotton from April to October. Throughout the year tree cultures (citrus, fruits) are cultivated.

\section*{Israel}

\section*{Irrigated area:}

The area equipped for irrigation as given by (Central Bureau of Statistics, 2003) and cited in (Siebert et al., 2005) is 183,408 ha for 2000 . The cultivated areas were drawn from the same source. The areas given in dunams were converted to hectares assumed that values were given in metric dunams, with 1 dunam \(=1,000\) square meter following (Wikipedia-Encyclopedia, 2006).

\section*{Cropping seasons:}

The seasons of Jordan of the FAO crop calendar for irrigated crops (FAO, 2005b) are assumed to be valid also in Israel, too. No main season can be determined there, but a summer cropping season between April and August is assumed. Wheat is grown as irrigated crop in winter from September to March, the rest of the annual field crops possibly on the same areas from April to August. Potatoes are grown from March until July. Vegetables are assumed to be grown in three seasons of equal length of 4 months starting in January with a cropping intensity of 3. Permanent crops are citrus, grapes, olives, dates, other fruit trees, and flowers and garden plants.

\section*{Lao People's Democratic Republic (PDR)}

\section*{Irrigated area:}

The area equipped for irrigation is for 2000 by (Ministry of Agriculture and Forestry - Department of Planning - Statistics Division, 2006), also cited in (Ministry of Agriculture and Forestry Department of Planning, 2002) and cited in (Siebert et al., 2005). There are 295,535 ha as the sum of wet season irrigated schemes. The harvested area for rice is 150,000 ha and vegetables with 18,000 ha are second most important crops. The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area FAO and (Ministry of Agriculture and Forestry - Department of Planning - Statistics Division, 2006).

\section*{Cropping seasons:}

The crop calendar is very similar to that of Thailand, only the cultivation seasons of rice (second season longer) and of cotton (during winter).

Main crop is rice that is irrigated twice on 75,000 ha from May to September (wet season) and from October to April (dry season). The second season was extended by 2 months, as the crop calendar for 2002 of the FAO GIEWS (FAO, 2005c) gives a longer kernel cultivation seasons.
Besides the permanent culture of sugarcane, as other crop vegetables are also irrigated from October to February, and cotton from August to February.

\section*{Lebanon}

\section*{Irrigated area:}

The area equipped for irrigation, \(117,113 \mathrm{ha}\), is the value cited for 1997 from (ESCWA, 1999) as cited in (Siebert et al., 2005). The cropped area was taken from the FAO AQUASTAT report (FAO, 1997c) and when no specific areas were available, also from the crop calendar for irrigated crops (FAO, 2005b). The values were scaled with the ratio of area equipped for irrigation of the 1990ies (FAO, 1997c) and for 1997 (ESCWA, 1999).

\section*{Cropping seasons:}

The seasons are taken basically from the FAO crop calendar for irrigated crops (FAO, 2005b) and are similar to those of Syria, but are shorter. Wheat is grown as irrigated crop in winter from November to March. Potatoes and tobacco are cropped during the standard summer season from May to September. Sugar beets start one month earlier in April, while groundnuts are grown from April to August. Fodder is grown from October to March. Vegetables are grown with a cropping intensity of 3 throughout the year, from January to April, May to August, and September to December. As permanent crops fruit trees, citrus, and bananas are cultivated.

\section*{Malaysia}

\section*{Irrigated area:}

The area equipped for irrigation, 362,600 ha, is the 1994 value of FAO (FAO, 1999) cited in (Siebert et al., 2005). The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was directly used, as (Siebert et al., 2005) used this figure to scale down the national total equipped area to the state level totals. Rice is dominating the crops on ca. 215,000 ha.

\section*{Cropping seasons:}

Main crop is rice that is irrigated twice from October to February and from May to September. According to (IRRI, 2005), the second cropping season is only present in the western part of Malaysia, the first also in the states of Sabah and Sarawak. All the other crops are irrigated also from May to September, besides the permanently cropped sugarcane and flowers.

\section*{Maldives}

\section*{Irrigated area:}

No irrigation is present on the Maldives (FAO, 1999).

\section*{Mongolia}

\section*{Irrigated area:}

The area equipped for irrigation is for 1993, with 57,300 ha area equipped for crops. 27,000 ha estimated for pasture are not considered here, but are cited in(FAO, 1995b) and (FAO, 1999), as cited in (Siebert et al., 2005). FAO mentions vegetables some fruits and early potatoes as main crops. Their areas are estimated according to the constraints given by the harvested areas in the FAOSTAT database (FAO, 2005d).

\section*{Cropping seasons:}

The crop calendar is similar to that of neighbouring north-eastern China.
Main crop is early potatoes, for which the cultivation season is assumed to start as early as in March and last until September, whereas vegetables are grown during the regular season from May to September. Permanent fruit orchards are assumed to include nut trees, the only tree fruit cited in FAOSTAT, and berries.

\section*{Myanmar}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,841,320 \mathrm{ha}\), was set to the one cited in (Stibig et al., 2003) and cited in (Siebert et al., 2005). The harvested area was taken from FAO crop calendar for irrigated crops (FAO, 2005b) as a starting point. The FAO AQUASTAT report (FAO, 1999) delivered more details. The special information of the Myanmar Ministry of Agriculture (Ministry of Agriculture Water Resources Utilisation Department) was assessed to be the most confident source, as it agreed with the area of irrigated rice of the FAO crop calendar and the areas cited in the AQUASTAT report. Only for vegetables and fruit trees that were only explicitly cited, the FAO calendar source was used and the rest of the area given by (Ministry of Agriculture - Water Resources Utilisation Department) distributed as annual crops.

\section*{Cropping seasons:}

Main crop is rice that is irrigated twice on roughly 940,000 ha from July to October (main season) and from November to March (second season). Seasons for spring-autumn rice and autumn-spring rice for the south of the crop calendar for the FAO GIEWS (FAO, 2005c) correspond well to this, like those for wheat and maize. All the other crops pulses, vegetables, also assumedly groundnut, sesame and jute are irrigated from March to July, besides cotton (February to August). Other annual cultures are assumed to grow during the winter season like wheat and maize from November to March. Permanent cultures of sugarcane and fruit trees exist.

\section*{Nepal}

\section*{Irrigated area:}

The area equipped for irrigation is \(1,168,348.60\) ha for \(2001 / 2002\) as given by (Central Bureau of Statistics, 2004)) and cited in (Siebert et al., 2005). Wheat is more important than rice as irrigated crop besides vegetables. The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area of (Central Bureau of

Statistics, 2004) and that from known sources (1,134,334 ha) as cited in the FAO AQUASTAT report on Asia (FAO, 1999), also cited in the FAO crop calendar for irrigated crops (FAO, 2005b).

\section*{Cropping seasons:}

Main crops are wheat and rice that are irrigated from November to May on roughly 615,000 ha and from June to October on roughly 500,000 ha, respectively. It is assumed that they are cultivated on the same areas. Oil crops (ca. \(24,000 \mathrm{ha}\) ) are repartitioned between mustard seed ( \(95 \%\) ) and linseed (ca. \(5 \%\) ) roughly according to their shares of harvested area in 1998-2002 in the FAOSTAT database (FAO, 2005d) and cropped with the same cropping season but greater share for mustard in the summer. As other cultures, maize and vegetables are grown from May to October. This fits well into the kernel seasons given by the FAO GIEWS crop calendar (FAO, 2005c). Permanent irrigated culture is sugar cane. The resulting percentage of monthly irrigation intensity is \(44 \%\).

\section*{Oman}

\section*{Irrigated area:}

The area equipped for irrigation per region is 72,630 ha for 2001 (Arab Organization for Agricultural Development - Agricultural Information, 2003a), close to the 72,714 ha mentioned for 2000 in (Ministry of National Economy, 2003) and both cited in (Siebert et al., 2005).

All cropped area is irrigated due to desert climatic reasons (FAO, 1997c). The crop areas are taken from the FAOSTAT database as mean harvested areas for the time period 1998-2002 (FAO, 2005d).

\section*{Cropping seasons:}

The seasons are assumed to be the same as for neighbouring Saudi-Arabia with similar climate. Wheat and assumedly barley are grown as irrigated crop in winter from December to June and from December to April, respectively. Sorghum and potatoes are possibly cropped on the same plots as wheat and barley from September to November and from July to November, respectively. Vegetables are grown in only one season from July to November. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3. Tobacco is assumed to be grown during the summer season from July to November. Alfalfa as forage and silage crop is assumed to be grown as a semi-permanent crop from January to December with cuts 3-4 months apart. As permanent crops dates and citrus are cultivated.

\section*{Qatar}

\section*{Irrigated area:}

The area equipped for irrigation, \(12,520 \mathrm{ha}\), is the value mentioned for 1993 in the FAO AQUASTAT report (FAO, 1997c) and cited in (Siebert et al., 2005).

All cropped area is irrigated due to desert climatic reasons (FAO, 1997c). The crop areas are taken from the FAOSTAT database as mean harvested areas for the time period 1998-2002 (FAO, 2005d).

\section*{Cropping seasons:}

The seasons are assumed to be the same as for neighbouring Saudi-Arabia with similar climate. Wheat and barley are grown as irrigated crops in winter from December to June and from December to April, respectively. Maize and potatoes are possibly cropped on the same plots as wheat and barley from July to November. Vegetables are grown in only one season from July to November. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3. Clover as forage crop is assumed to be grown only from December to April. As permanent crops dates, citrus, and grapes are cultivated.

\section*{Pakistan}

\section*{Irrigated area:}

The area equipped for irrigation, \(14,417,464 \mathrm{ha}\), was set to the one mentioned for 2000 by the agricultural census (Government of Pakistan - Statistics Division - Agricultural Census Organization, 2003) as cited in (Siebert et al., 2005) and used in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). The census also lists irrigated and non-irrigated harvested areas per crop for wheat, paddy rice, cotton, maize for grain, sugarcane, potatoes, oilseed, pulses, fodder and vegetables including potatoes. In addition to \(23,439,748\) ha harvested area of annual crops cropped in "kharif" ( \(10,394,203\) ha, sowing in autumn) and "rabi" ( \(12,665,006\) ha, sowing in spring) crop seasons, 380,521 ha of fruit orchards are cited. For crops not cited in the census, like barley, millet, sorghum, rapeseed and citrus, the original harvested area cited by the FAO crop calendar (FAO, 2005b) was scaled with the corresponding ratio of equipped area from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) and that cited by FAO. The distribution of oil seed area cited in the agricultural census to classes besides rapeseed that is used in the own data set was unclear. Therefore, the scaled area of rapeseed replaced the area of the class oilseeds. The final fruit tree orchard area ( \(199,948 \mathrm{ha}\) ) was calculated as the value for fruit orchards, cited in the agricultural census and assumed to be \(100 \%\) irrigated, minus the scaled area of citrus that was assumed to be contained in the former area. The final vegetables area ( \(335,121 \mathrm{ha}\) ) was calculated as the census area including potatoes minus the census area for potatoes.

\section*{Cropping seasons:}

The agricultural census (Government of Pakistan - Statistics Division - Agricultural Census Organization, 2003) mentions for annual crops the relative distribution of total crop area, irrigated and rainfed, for the "kharif" and "rabi" season. They are given either as relative percentages of crop area (wheat, rice, cotton, maize for grain, and sugarcane) or as absolute areas (potatoes, oil seed, pulses and fodder). This mixture of rainfed and irrigated areas could not be separated to form cropping seasons for irrigated crops. Therefore, the FAO crop calendar (FAO, 2005b) was used. In the "kharif" autumn sowing season, irrigated wheat is grown from November to May. Similarly, rapeseed and fodder are cultivated from November to May. In the "rabi" spring sowing season, all the other annual crops are grown from June to October, besides cotton from June to December. Throughout the year sugarcane and tree cultures (citrus, fruits) are cultivated.

\section*{Palestine}

\section*{Irrigated area:}

The area equipped for irrigation is 19,466 ha for the area of occupied Palestinian Territories, i.e. Gaza Strip and West Bank. The value as cited in (Siebert et al., 2005) comprises 16,222 ha for 2001
as given by Palestinian statistics (Palestinian National Authority - Palestinian Central Bureau of Statistics, 2003) and ca. 3,200 ha of Israeli settlements in Gaza Strip and West Bank as cited by the statistics of Israel (Central Bureau of Statistics, 2003). The cultivated areas were drawn from (Palestinian National Authority - Palestinian Central Bureau of Statistics, 2004). The areas given in dunums were converted to hectares assumed that values were given in metric dunums, with 1 dunum \(=1,000\) square meter following (Wikipedia-Encyclopedia, 2006). Next, the values were scaled with the ratio of the total 19,466 ha to the 16,222 ha equipped area under Palestinian authority only.

\section*{Cropping seasons:}

The seasons of Jordan of the FAO crop calendar for irrigated crops (FAO, 2005b) are assumed to be valid also in Palestine, too. No main season can be determined there, but a summer cropping season between April and August is assumed. Wheat is grown as irrigated crop in winter from September to March, barley, pulses, other annual field crops and maize possibly on the same areas from April to August. Potatoes are grown from March until July. Vegetables are assumed to be grown in three seasons of equal length of 4 months starting in January with a cropping intensity of 3. Clover is assumed to be cultivated as fodder during winter from September to February. Permanent crops are citrus, dates, grapes and other fruit trees.

\section*{Papua New Guinea}

\section*{Irrigated area:}

There is no irrigation according to FAO (FAO, 1999).

\section*{Philippines}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,550,000 \mathrm{ha}\), was set to the one mentioned for 1993 by (National Irrigation Administration, 1993), cited by (FAO, 1999) and cited in (Siebert et al., 2005). The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) were directly used, as now newer information was available.

\section*{Cropping seasons:}

The crop calendar is mostly identical to that of Thailand, besides shorter rice cropping seasons. Main crop is rice that is irrigated twice on ca. 900,000 ha from May to September and from October to February. Besides vegetables that are also irrigated from October to February, the other crop cited (sugarcane) is irrigated throughout the year.

\section*{Saudi-Arabia}

\section*{Irrigated area:}

The area equipped for irrigation is \(1,730,767\) ha, derived as the maximum values for 2000 and 1992 from sources (Arab Organization for Agricultural Development - Agricultural Information, 2003b) and (Dabbagh and Abderrahman, 1997) as cited in (Siebert et al., 2005).

All cropped area is irrigated due to desert climatic reasons (FAO, 1997c). The crop areas are taken from the FAOSTAT database as mean harvested areas for the time period 1998-2002 (FAO, 2005d).

\section*{Cropping seasons:}

The seasons are taken basically from the FAO crop calendar for irrigated crops (FAO, 2005b) and validated by the FAO GIEWS crop calendar (FAO, 2005c). Wheat and barley are grown as irrigated crop in winter from December to June and from December to April, respectively. Maize and potatoes are possibly cropped on the same plots as wheat and barley from July to November. Vegetables are grown in only one season from July to November. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3. Groundnuts, pulses, sesame seed are equally assumed to be equally grown from July to November. Unspecified forage crops are grown only from December to April, whereas alfalfa (classified as managed grassland) is grown as semi-permanent crop throughout the year. As permanent crops dates, citrus, and grapes are cultivated.

\section*{Sri Lanka}

\section*{Irrigated area:}

The area equipped for irrigation, 570,000 ha, was set to the one cited for 1995 by (FAO, 1999) and by (Siebert et al., 2005) found to be the best for downscaling. The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was directly used, as no change in equipped area was present.

\section*{Cropping seasons:}

Main crop is rice that is irrigated twice from November to March and from June to October. All the other crops are irrigated also from June to October, besides the permanently cropped sugarcane.

\section*{Syria}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,266,900\) ha, is the value cited for 2001 from (Arab Organization for Agricultural Development - Agricultural Information, 2003c) as cited in (Siebert et al., 2005). The cropped area was taken from the FAO crop calendar for irrigated crops (FAO, 2005b) and scaled with the ratio of area equipped for irrigation of the 1990ies (FAO, 1997c) and for 2001 (Arab Organization for Agricultural Development - Agricultural Information, 2003c).

\section*{Cropping seasons:}

The seasons are taken basically from the FAO crop calendar for irrigated crops (FAO, 2005b). Wheat is grown as irrigated crop in winter from November to May. All the other annual irrigated crops (maize, barley, potatoes, pulses, vegetables, oil crops (assumed to be sesame), groundnuts, sunflower, tobacco) are grown in the summer season from June to October, besides sugar beets that start already in May and cotton that is grown from May to November. Fodder crops are grown from December to April. As permanent crops fruits and citrus are cultivated.

\section*{Taiwan, Province of China}

\section*{Irrigated area:}

The area equipped for irrigation, \(525,528 \mathrm{ha}\), is the value mentioned for 1995 in (DirectorateGeneral of Budget, 1997) as cited in (Siebert et al., 2005).

The harvested areas cited in (Directorate-General of Budget, 1997) were taken as a reference. It was assumed that only rice, sugar cane and vegetables were irrigated, as for the other crops no detailed statistical data were present. (Achtnich, 1980) mentions also maize, sweet potatoes, fruits, and tobacco as irrigated crops.

\section*{Cropping seasons:}

The seasons are assumed to be the same as for neighbouring south-eastern China (e.g. province of Fujian). Rice is cropped twice on the same area from May to October and from November to March with a cropping intensity of 2 . Vegetables are grown from April to August. As permanent crop sugarcane is grown throughout the year.

\section*{Tajikistan}

\section*{Irrigated area:}

The area equipped for irrigation, 719,200 ha, was set to the figure for 1994 from (FAO, 1997b) and confirmed by (USAID, 2002) as cited in (Siebert et al., 2005).. The original harvested area cited by FAO (FAO, 1997b) was taken as a starting point, as the sum is the area equipped for irrigation. In (FAO, 1997c), additional information on crops are given. The figures for harvested area from the FAOSTAT database (FAO, 2005d) for the available time period 1992-1995 were taken as a reference, as indicated by the following fact: The rounded irrigated area of cotton corresponds exactly to the harvested area. For most of the crops, an irrigation ratio of \(100 \%\) was assumed. As fodder crops, only maize and grasses were assumed to be irrigated, as for these crops figures by FAOSTAT are given and other crops could not directly to be identified as fodder crops. For the moment grasses for fodder are classified as managed grassland and not considered for the modelling. Rice is not explicitly cited, so FAOSTAT data was used. The FAOSTAT harvested area of cereals for maize, rye and oats was similarly taken, as the irrigated areas cited by (FAO, 1997b) were much higher (factors 3 and 10!). To the contrary, irrigated areas for barley and wheat seemed realistic, with \(50 \%\) and \(30 \%\) irrigation ratio. Summing all "other annual" crops, a share of roughly \(50 \%\) of the figure given in (FAO, 1997b) was flatly attributed to modelling group "others annual", with approximately \(15 \%\) irrigation ratio. As permanent crops, all citrus, grapes and fruit trees were assumed to be irrigated.

\section*{Cropping seasons:}

The crop calendar for Afghanistan was used as a starting point for neighbouring mountainous Tajikistan and Kyrgyzstan.

In the winter season, irrigated wheat is grown from November (Kyrgyzstan: October) to May according to the FAO GIEWS crop calendar (FAO, 2005c), like in Afghanistan. Similarly, barley is cultivated from December to April, rye and oats from November to April. All the other annual crops are summer crops assumed to be grown from July to October (rice, soybeans, sunflower, potatoes (different to Afghanistan), pulses, melons, other annuals). Maize (including maize for fodder) is grown from May until October according to the FAO GIEWS crop calendar (FAO, 2005c), different to Afghanistan, cotton from May until November. The rest of fodder was
assumed to be annual cultures to be potentially irrigated all over the year (mixed grasses, other grasses).

\section*{Thailand}

\section*{Irrigated area:}

The area equipped for irrigation, \(4,985,708\) ha, was set to the one mentioned for 2000 by (Office of Agricultural Economics - Thailand, 2005) and cited in (Siebert et al., 2005). The original harvested area cited by the FAO crop calendar for irrigated crops (FAO, 2005b) was scaled with the corresponding ratio of equipped area FAO and (Office of Agricultural Economics - Thailand, 2005).

\section*{Cropping seasons:}

Main crop is rice that is irrigated twice on ca. 2.2 Mha from May to October (extended by 1 month the date of (FAO, 2005b) according to major rice season of (Office of Agricultural Economics Thailand, 2005) and from October to April (extended by 2 months the date of (FAO, 2005b) per 1 month according to minor rice season of (Office of Agricultural Economics - Thailand, 2005)). Besides vegetables that are also irrigated from October to February, all the other crops (sugarcane, bananas, citrus, fruit tree orchards) are irrigated throughout the year.

\section*{Turkmenistan}

\section*{Irrigated area:}

The area equipped for irrigation, \(1,744,100 \mathrm{ha}\), was set to the figure for 1994 from (FAO, 1997b) and cited in (Siebert et al., 2005). The original harvested area cited by FAO (FAO, 1997b) was taken as a starting point, as the sum is the area equipped for irrigation, i.e. the maximum area. The figures for harvested area from the FAOSTAT database (FAO, 2005d) for the available time period 1992-1995 were taken as a reference, as indicated by the following fact: The rounded irrigated area of cotton corresponds nearly exactly to the harvested area. For most of the crops, an irrigation ratio of \(100 \%\) was assumed. As fodder crops, only maize and grasses plus vegetables/roots for fodder (ca. \(60 \%\) irrigation ratio) were assumed to be irrigated, as for these crops figures by FAOSTAT are given and other crops could not directly to be identified as fodder crops. For the moment grasses for fodder are classified as managed grassland and not considered for the modelling. Rice is cited, but the FAOSTAT data were used, as they give a smaller value that was assumed to be a more realistic estimation for the actually irrigated area. The FAOSTAT harvested area of cereals for maize, rye and wheat was similarly taken, as the irrigated area cited by (FAO, 1997b) for wheat was much higher (factor 2), likewise assumed to be maximum equipped areas for cereals. To the contrary, irrigated area for barley seemed realistic, with \(50 \%\) irrigation ratio. Like for Tajikistan, potatoes, pulses, melons and vegetables were assumed exist as \(100 \%\) irrigated crops. The rest of the value for annual crops given in (FAO, 1997b) is about 75,000 ha and was assumed to be filled by cereals barley ( \(40,000 \mathrm{ha}\) ) and grain maize ( \(43,000 \mathrm{ha}\) ) and rye (ca. 600 ha ) and by areas foreseen for wheat or for perennial crops. As permanent crops, all grapes and fruit trees were assumed to be irrigated. Nevertheless with roughly 34,000 ha they reached by far not the equipped area of ca. 233,000 ha.

\section*{Cropping seasons:}

The crop calendar for Tajikistan was assumed to be valid for neighbouring Turkmenistan, too.

In the winter season, irrigated wheat is grown from November to May according to the FAO GIEWS crop calendar (FAO, 2005c). Similarly, barley is cultivated from December to April, rye from November to April. All the other annual crops are summer crops assumed to be grown from July to October (rice, potatoes, soybeans, pulses, melons, other annuals). Maize (including maize for fodder) is grown from May until October according to the FAO GIEWS crop calendar (FAO, 2005c), cotton from May until November. The rest of fodder was assumed to be annual cultures to be potentially irrigated all over the year (mixed grasses, vegetables and roots for fodder).

\section*{United Arab Emirates}

\section*{Irrigated area:}

The area equipped for irrigation, 280,341 ha, is the value mentioned for 2001 in (Ministry of Planning, 2003) and cited in (Siebert et al., 2005).

All cropped area is irrigated due to desert climatic reasons (FAO, 1997c). The crop areas are taken from the FAOSTAT database as mean harvested areas for the time period 1998-2002 (FAO, 2005d).

\section*{Cropping seasons:}

The seasons are assumed to be the same as for neighbouring Saudi-Arabia with similar climate. Wheat is grown as irrigated crop in winter from December to. Potatoes are possibly cropped on the same plots as wheat from September to November. Vegetables are grown in only one season from July to November, as indicated by the 9,683 ha irrigated area for vegetables only for the 2000-2001 cropping season given by the national statistics (Ministry of Planning, 2003) that corresponds to 9,576 ha given in the FAOSTAT database for 2001. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3 . Tobacco is assumed to be grown during the summer season from July to November. Grasses for forage and silage are assumed to be grown from December to April. Alfalfa as forage and silage crop (classified as managed grassland) is assumed to be grown as a semi-permanent crop from January to December with cuts 3-4 months apart. As permanent crops dates, citrus, and grapes are cultivated, also others (mangoes, figs, tree-nuts, and bananas).

\section*{Uzbekistan}

\section*{Irrigated area:}

The area equipped for irrigation, \(4,223,000 \mathrm{ha}\), was set to the figure for 1996 from (European Commission - Directorate General, 1996) and cited in (Siebert et al., 2005). The original harvested area for 1993 cited by FAO (FAO, 1997b) was taken as a starting point, as the sum ( \(4,308,800 \mathrm{ha}\) ) is slightly higher than the area equipped for irrigation. The figures for harvested area from the FAOSTAT database (FAO, 2005d) for the available time period 1992-1995 were taken as a reference, as indicated by the following fact: The rounded irrigated area of cotton corresponds nearly exactly to the harvested area. For most of the crops, an irrigation ratio of \(100 \%\) was assumed. As fodder crops, only maize and grasses plus vegetables/roots for fodder (ca. \(95 \%\) irrigation ratio) were assumed to be irrigated, as for these crops figures by FAOSTAT are given and other crops could not directly to be identified as fodder crops. For the moment grasses for fodder are classified as managed grassland and not considered for the modelling. For wheat and potatoes, the originally cited harvested areas were taken, as they are smaller than the harvested areas of

FAOSTAT (50 \% and \(60 \%\) irrigation ratio). Rice is cited, but like for maize the FAOSTAT data were used, as they give assumedly a more realistic estimation for the actually irrigated area, even if they are higher. The FAOSTAT harvested area of other cereals (ca. 45,000 ha) rye, barley, millet and sorghum was scaled to the value given in Figure 9 of (FAO, 1997b), by applying irrigation ratios of \(50 \%\) and \(12.5 \%\) (barley). Like for Turkmenistan, pulses and sunflowers were assumed to exist besides potatoes, melons and vegetables as \(100 \%\) irrigated crops. The rest of the value for perennial crops given in (FAO, 1997b) was assumed to be much to high, as permanent crops, all fruit trees and berry orchards, grapes and citrus were assumed to be irrigated, nevertheless with roughly 230,000 ha by far not reaching the equipped area of about 678,000 ha.

\section*{Cropping seasons:}

The crop calendar for Tajikistan was assumed to be valid for neighbouring Uzbekistan like for Turkmenistan, too.

In the winter season, irrigated wheat is grown from November to May according to the FAO GIEWS crop calendar (FAO, 2005c). Similarly, barley is cultivated from December to April, rye from November to April. All the other annual crops are summer crops assumed to be grown from July to October (rice, potatoes, sunflower, soybeans, pulses, melons, other annuals). Maize (including maize for fodder) is grown from May until October according to the FAO GIEWS crop calendar (FAO, 2005c), cotton from May until November. The rest of fodder was assumed to be annual cultures to be potentially irrigated all over the year (mixed grasses, vegetables and roots for fodder). Perennial crops are fruits and berry orchards, grapes and small areas of citrus.

\section*{Viet Nam}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,000,000 \mathrm{ha}\), was set to the one cited for 1994 by (FAO, 1999). The harvested area for rice of 5.46 Mha and for vegetables of roughly 380,000 ha is cited in the FAO AQUASTAT report (FAO, 1999). The rice harvested area is calculated from an equipped area of 2.1 Mha multiplied by a cropping factor of 2.6. The area does not correspond to the harvested area cited by FAO crop calendar for irrigated crops (FAO, 2005b), that probably was calculated on the basis of an cropping intensity of roughly 2. In (World Bank, 1996b), an area of 5.4 Mha harvested irrigated paddy rice is cited, out of 6.4 million totally harvested paddy area. The first number is identical to the FAO AQUASTAT report value. According to the World Bank, in 1996, out of 4 million cultivated irrigated area, 3 Mha were irrigation design area, and 2 Mha each were irrigated and not-irrigated, i.e. area equipped for irrigation was planned to increase by \(50 \%\) area (see (World Bank, 1996b) page 22, e.g. Figure 4.2). The same source also mentions that even if the reported cropping intensity is 2.6 , the actual one is closer to 2.0 . For the Mekong delta double and triple cropping in some areas exist (see source on page 76). The paddy rice harvested area as cited in the FAOSTAT database (FAO, 2005d) shows an increase from 1990 until 2002. The mean is roughly 6.45 million for 1990-1995 and 7.54 million for 1998-2002. Therefore, for vegetables an area of roughly 380,000 ha for 1997 in (FAO, 1999) was taken as a new reference, and the other crop area including rice ( 4.5 Mha , with a cropping intensity of 2 ) was taken from the FAO crop calendar for irrigated crops (FAO, 2005b), as no change in equipped area could be found in references.

\section*{Cropping seasons:}

Main crop is rice that is irrigated twice on 2.25 Mha from May to September and from October to February. The crop calendar for FAO GIEWS (FAO, 2005c) gives somewhat different cultivation
seasons, but seasons for spring-autumn rice and autumn-spring rice for the south correspond well. Only seasons of ten moth rice are a little bit longer, but are assumed to be negligible within the scope of global modelling. All the other crops besides the permanent cultures of sugarcane, bananas, and citrus are also irrigated from October to February (maize, sweet potatoes, and vegetables).

\section*{Yemen}

\section*{Irrigated area:}

The area equipped for irrigation, 388,000 ha, is the value mentioned for 1996 from (World Bank Rural Development, 1999) excluding spate irrigation, as cited in (Siebert et al., 2005). The cropped area was taken basically from the FAO crop calendar for irrigated crops (FAO, 2005b). For fodder, from the FAOSTAT database mean harvested areas for the period 1990-1995 were taken and the irrigated area distributed to sorghum for fodder and alfalfa for forage and silage, assuming that other grasses were cultivated as rainfed cultures only.

\section*{Cropping seasons:}

The seasons are taken basically from the FAO crop calendar for irrigated crops(FAO, 2005b) and validated by the crop calendar for neighbouring Saudi-Arabia. Wheat is grown as irrigated crop in winter from November to May, barley and millet from December to April. Maize, sorghum, potatoes, pulses, sesame and tobacco are grown from June to October. Maize and sorghum are possibly cropped on the same plots as wheat, barley, and millet. Vegetables are grown in only one season from June to October. Theoretically they could be cropped in three seasons of equal length of 4 months starting in January with a cropping intensity of 3. Cotton is grown from May to November. Unspecified forage crops are grown only from December to April, whereas alfalfa (classified as managed grassland) is grown as semi-permanent crop throughout the year. As permanent crops fruits, coffee, citrus and bananas are cultivated.

\section*{EUROPE}

For many European countries the Statistical Office of the European Communities (EUROSTAT) cites area equipped for irrigation and actually irrigated area. The latter is given as total area irrigated once a year and as crop-specific area for the non-exhaustive crop list durum wheat, maize, potatoes, sugar beet, sunflower, soybeans, fodder plants, fruit and berry orchards, citrus and vines (EUROSTAT, 2005).

\section*{Albania}

\section*{Irrigated area:}

Current areas equipped for irrigation ( 340,000 ha, according to AQUASTAT) and actually irrigated ( \(180,000 \mathrm{ha}\) ) of (Brewer, 2001) were take as the best guess reference. His areas are in line with somewhat older sector reviews of the World Bank (World Bank, 1994) and (World Bank, 1999). He lists as main crops maize, alfalfa, vegetables and watermelon, in line with the list of irrigated crops of 1990 from FAO sector review (FAO, 1992). The latter list was taken, the corresponding harvested areas for the year 2000 from the FAOSTAT database (FAO, 2005d) transformed to absolute irrigated crop areas with estimated percentages, until fitting the current area of (Brewer, 2001) taken as representative for 2001. Irrigated harvested area was estimated with a cropping intensity of 1 , also for vegetables, assuming that some non-irrigated vegetable area remains, so that the harvested area from the FAOSTAT database (FAO, 2005d) is not fully reached.

\section*{Cropping seasons:}

In winter, only winter wheat and oats are irrigated from November to June. Irrigated crops are mainly summer crops, also cotton, grown between April and September. Rice is grown from May to September. Potatoes are grown from March to September according to the crop calendar for the FAO GIEWS (FAO, 2005c). Vegetables are grown from March until November. Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer, like grapes and olives in summer.

\section*{Andorra}

\section*{Irrigated area:}

Current areas equipped for irrigation, 150 ha, and actually irrigated ( 150 ha ) were taken from the CORINE Land Cover 1990 data base (European Environment Agency, 2000) and assumed to be of identical size. Agricultural area was taken from (Wikipedia-Encyclopedia, 2005a), and repartitioned to crops maize, grapes and tobacco in ascending order of assumed importance in the list given by (Infoplease, 2005). Irrigated harvested area was estimated with a cropping intensity of 1, as no values in the FAOSTAT database (FAO, 2005d) are present.

Only national data on irrigated areas are available.

\section*{Cropping seasons:}

Irrigation calendar is assumed to be the same for Andorra and for France.
Irrigated crops are only summer crops grown between May and September: maize and tobacco. Rice is grown from May to September. Maize, maize for fodder, potatoes and sugar beets are grown
from April until October. Vegetables are grown from March until November. Grapes are grown throughout the year and irrigated against water deficiency in summer.

\section*{Austria}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 97,480 ha and actually irrigated \(34,230 \mathrm{ha}\) ) are for 2003 and consistent with literature values in (Neudorfer, 2003). Crop list was taken from (Baldock et al., 2000) and potatoes as ubiquitous crop for central an eastern Europe added, in accordance with (Neudorfer, 2003) and (Katzmayer and Rennert, 2003). The relative percentages of the classes were estimated following (Neudorfer, 2003) and (Katzmayer and Rennert, 2003), with the highest area values attributed to sugar beets cited by (Huettler, 1996). Irrigated harvested area was estimated with a cropping intensity of 1 , only for vegetables the area given in the FAOSTAT database (FAO, 2005d) was rounded and used, with an intensity of roughly 2.

Sub-national data on irrigated areas are available for the EUROSTAT crop list

\section*{Cropping seasons:}

Irrigation calendar is assumed to be similar to that of Slovakia.
Potatoes and sugar beets are grown from May to October. Vegetables are grown from March to October in two cropping seasons of increasing area (March - June, July - October). Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes / vines are grown throughout the year and also irrigated against water deficiency in summer.

\section*{Belarus}

\section*{Irrigated area:}

Latest available data on irrigated crops is for 1993 in an FAO AQUASTAT report (FAO, 2005a). The 115,000 ha equipped for irrigation and actually irrigated are distributed according to relative percentages derived from absolute values for 1990 (148,200 ha) given there.

The distribution of area of these classes to crops and subgroups of own nomenclature was done according to repartitioning of harvested area for 1993 from the FAOSTAT database (FAO, 2005d): Cereals and pulses to \(10 \%\) oats, \(45 \%\) barley, \(40 \%\) rye, \(5 \%\) pulses irrigated, wheat having a relatively small area of around 100,000 ha such as pulses. The latter were included as they are cited in the class name and therefore assumed to be definitely present. Vegetables ( 65,000 ha harvested area) and potatoes ( 690,000 ha harvested area) irrigated areas were distributed the same way to be covered \(80 \%\) by potatoes and 20 by \(\%\) vegetables. Fodder crops were taken to be \(100 \%\) maize, given the harvested area as high as for oats, \(1 / 3\) of those of barley and rye. For all of these mentioned crops, the assumed irrigated harvested areas were calculated with a cropping intensity of 1 , only for vegetables an intensity of 2 was assumed. Nevertheless, the FAOSTAT harvested areas are by far not reached. Irrigated industrial crops were assumed to be \(100 \%\) flax, having a relatively high area compared to potatoes (Marks, 1992).

Only national data are available.

\section*{Cropping seasons:}

Irrigation calendar is assumed to be similar to that of Moldova.
As irrigated winter cereals barley, rye and oats are grown from November to June. The greater share of summer crops (maize for forage, potatoes) are generally grown within the season between April and October: Maize from April to September, pulses and potatoes from April to October. Industrial crops (assumed to be flax) are grown from May to October. Vegetables are grown on the same areas in two separate cropping seasons (April - June, July - October) on the same area. Managed grassland is cultivated throughout the year and irrigated against dryness in summer.

\section*{Belgium}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area equipped for irrigation, \(35,170 \mathrm{ha}\), is for 2003. The actually irrigated area, roughly \(6,500 \mathrm{ha}\), was taken from the agricultural census of 2003 (Direction générale Statistique et Information économique of Belgium, 2004). Major areas are maize (ca. 1,100 ha), potatoes (ca. 700 ha ), other annual crops that were assumed to be vegetables (ca. \(3,900 \mathrm{ha}\) ). Irrigated harvested area was estimated with a cropping intensity of 1 , only for vegetables with an intensity of 2 , assuming oceanic climate mildness prolonging the vegetation season.

Sub-national data on irrigated areas per crop are available from the agricultural census of 2003, but not from those of the years 2004 and 2005.

\section*{Cropping seasons:}

Irrigation calendar is assumed to be similar to that of the Netherlands.
Irrigated crops are summer crops. Maize is grown in the standard season from May to October. Potatoes and sugar beets are grown from April to October. Vegetables are grown on the same areas in two separate cropping seasons (March - June, July - October). Fruit and berry orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer.

\section*{Bosnia and Herzegovina}

\section*{Irrigated area:}

Current areas equipped for irrigation was set to be the 4,630 ha cited in (Civil Society Promotion Center, 2002), while the value for the areas actually irrigated ( \(3,000 \mathrm{ha}\) ) was taken from the uniform figure (World Bank, 2003b) assuming that the cited extent of around 3,000 ha large-scale irrigation in Ljubuski Polje is representative for the total area actually irrigated including small-scale irrigation in Neretva River alluvium, seasonal irrigation in other areas, and the early crop production in Dubrava Plateau. The crops are repartitioned for the year 2000 to the gross land covers cited in (Agency for Statistics of Bosnia and Herzegovina, 2002) using estimated relative percentages based on harvested area and estimated irrigated share for the high-income crops potatoes ( \(40 \%\), also for subsistence), and vegetables ( \(40 \%\) ), maize ( \(15 \%\) ), and tobacco ( \(5 \%\) ) that are cited as crops in (Agency for Statistics of Bosnia and Herzegovina, 2001). Irrigated harvested area was estimated with a cropping intensity of 1 , also for vegetables, as indicated in the figures of nearly identical sown areas and harvested areas in (Agency for Statistics of Bosnia and

Herzegovina, 2001). The resulting harvested areas are far less below those given in the FAOSTAT database (FAO, 2005d).

Only national data on irrigated areas were used, as also no data on the district of Brcko, the third entity besides the Federation of Bosnia and Herzegovina and the Republika Srpska area given in the national statistics.

\section*{Cropping seasons:}

Irrigation calendar is assumed to be the same for Bosnia and Herzegovina, Croatia, and Serbia and Montenegro.

Vegetables are cultivated during a relatively long cropping season from March to October. The cropping season for maize starts in April and ends in September. The cropping season of sugar beets and potatoes starts in April, that for tobacco starts in May and both end in October. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes \(/\) vines are grown throughout the year. Meadows are assumed to be managed grassland grown or cultivated throughout the year and possibly actually irrigated in the summer.

\section*{Bulgaria}

\section*{Irrigated area:}

The area equipped for irrigation, 545,160 ha, was taken from (Ministry of Agriculture and Forestry, 2004) Another national source (Chehlarova-Simeonova et al., 2006) specifies 37,001 ha mean actually irrigated area. These values were assumed to be more confidential, as they are derived from a time series and from national expertise, than the EUROSTAT data with area equipped for irrigation of 124,490 ha and actually irrigated area of 79,370 ha for 2003 (EUROSTAT, 2005), much less than literature data for 1990 (Republic of Bulgaria - Council of Ministers, 1999). The EUROSTAT list of crops was extended by crops cited in (Achtnich, 1980) and (ChehlarovaSimeonova, 2001). Fodder crops are assumed to be maize (cited in the FAOSTAT database (FAO, 2005d)). FAOSTAT harvested areas for rice and cotton were assumed to be fully irrigated areas. Irrigated harvested area was estimated with a cropping intensity of 1, only for vegetables with an intensity of 2 , assuming sub-humid winter warm climate.

Sub-national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

Irrigation calendar is assumed to be the similar to that of Romania.
Irrigated crops are summer crops mainly grown from May to October. Durum wheat is grown from April to July, maize from April to September, potatoes and sugar beets from April to October. Rice is grown from June to October. Vegetables are grown in two cropping seasons with the same area (March-June and July-October). Grapes, fruit orchards and alfalfa are assumed to be cultivated throughout the year, with irrigation during dry weather conditions. Seed cotton, like tobacco (classified as others annual) is grown between May and October.

\section*{Croatia}

\section*{Irrigated area:}

Current area equipped for irrigation, 5,790 , ha for 1996 is specified by (CRCID, 2005). The area actually irrigated ( \(5,000 \mathrm{ha}\) ) was taken from the uniform figure of irrigated land of the Agricultural Census 2003 (as of 1 June 2003) (CROSTAT, 2003). The crops are distributed for the year 2003 to the gross land covers cited in the Agricultural Census 2003 (CROSTAT, 2003) using estimated relative percentages from the high-income crops maize, grapes, potatoes, vegetables and fruit orchards that are cited as crops in the harvested areas in the FAOSTAT database (FAO, 2005d). Irrigated harvested area was estimated with a cropping intensity of 1, also for vegetables, as indicated in the figures of nearly identical sown areas and harvested areas in the neighbouring Bosnia and Herzegovina (Agency for Statistics of Bosnia and Herzegovina, 2001). As in the case of the neighbouring country, the resulting harvested areas are far less below those given in the FAOSTAT database (FAO, 2005d).

Detailed sub-national data on irrigated areas are available on municipality area level (CROSTAT, 2003).

\section*{Cropping seasons:}

Irrigation calendar is assumed to be the same for Bosnia and Herzegovina, Croatia, and Serbia and Montenegro.

Vegetables are cultivated during a relatively long cropping season from March to October. The cropping season for maize starts in April and ends in September. The cropping season of sugar beets and potatoes starts in April, that for tobacco starts in May and both end in October. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes / vines are grown throughout the year. Meadows are assumed to be managed grassland grown / cultivated throughout the year and possibly actually irrigated in the summer.

\section*{Cyprus}

\section*{Irrigated area:}

The data on equipped irrigated area ( 44,930 ha for Greek part (EUROSTAT, 2005) and 55,813 ha for total Cyprus according to (Siebert et al., 2005)) and on the actually irrigated area 35,410 ha (EUROSTAT, 2005) are for 2003. The actually irrigated area corresponds well to FAO AQUASTAT data (FAO, 2005a) and (FAO, 1997c). Crop list for rest of actually irrigated area that is not included in the EUROSTAT list of crops (Durum wheat, maize, potatoes, sugar beet, sunflower, soybeans, fodder plants, fruit and berry orchards, citrus and vines) was taken for 1994 from (FAO, 1997c) and FAOSTAT database of harvested area for 2000 and 2003 (FAO, 2005d). In a first step, the areas from the AQUASTAT report for barley (main cereal besides durum wheat cited by EUROSTAT), pulses, vegetables, and other annual crops including oil crops, and also fruit trees other than citrus were scaled to fit the area total of EUROSTAT. Final areas of these crops were adjusted then to fit within the harvested area of FAOSTAT database with the following sequence of importance: vegetables (high harvested area of \(4,400 \mathrm{ha}\), with a maximum irrigated area of 3,600 ha for the larger cropping season), almond trees (perennial, high harvested area of 3,600 ha, specifically cited), olives (perennial, high harvested area of 3,300 ha), barley (specifically cited), pulses (specifically cited), others annual (high irrigated area, specifically cited). Irrigated
harvested area was estimated with a cropping intensity of 1, only for vegetables fit to FAOSTAT data with an intensity of 1.25 .

Only national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

In winter, only barley is irrigated from November to May. Irrigated crops are mainly summer crops, grown between April and September. Potatoes are grown from February to June, according to the FAO GIEWS crop calendar (FAO, 2005c). Others annual are grown from April until September. Vegetables are grown from February to November on the same area in two cropping seasons, mainly as early vegetables (Februar - June and July - November). Fruit orchards and specifically cited almond trees are assumed to be frost-irrigated and irrigated against water deficiency in summer, like citrus, grapes, olives, and irrigated fodder. Fodder is assumed to be managed grassland, as fodder maize according to the harvested area from the FAOSTAT database is negligible (FAO, 2005d).

\section*{Czech Republic}

\section*{Irrigated area:}

The area equipped for irrigation, \(50,590 \mathrm{ha}\), of the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) is based on sub-national data of EUROSTAT for 2003 and 2005 (EUROSTAT, 2006). Actually irrigated area was 16,860 ha for 2003 and 17,320 ha for 2005 according to EUROSTAT, while (Miskovsky, 2001) lists 16,238 ha for 1997. Thus, the actually irrigated area (16,554 ha) representative for the period 1998-2002 was calculated as mean of the values for 1997 and 2003. A list of irrigated crops is cited for privatised irrigation systems for vegetables and fruits (e.g. strawberries and fruit tree orchards) by (Miskovsky, 2001). According to (Štastná et al., 2006) irrigation is nowadays only being used for crops that cannot be grown without irrigation or for those for which irrigation generates high added value (vegetables, hop-fields, orchards, vineyards and potatoes). This latter list is used together with FAOSTAT data of harvested area for 1998-2002 (FAO, 2005d) and the irrigated crop areas in neighbouring countries Austria and Germany to distribute the total to the crop groups: Vegetables (assumed \(50 \%\) of irrigated area, ca. \(8,300 \mathrm{ha}\),), fruit and berry orchards (ca. 3,300 ha, \(20 \%\) ), hops, vineyards, potatoes (each ca. 1,700 ha or \(10 \%\) ). Irrigated harvested area was estimated with a cropping intensity of 1.

Sub-national data on total actually irrigated areas are available for regions from EUROSTAT.

\section*{Cropping seasons:}

Irrigated crops are mainly summer crops. Vegetables and potatoes are grown from April to October. Permanent crops fruit and berry orchards, Grapes / vines, and hops are assumed to be frost-irrigated (fruits) and irrigated against water deficiency in summer.

\section*{Denmark}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 476,000 ha and actually irrigated 201,480 ha) are for 2003. Crop list for rest of actually irrigated area that is not included in EUROSTAT list of crops was taken from (Achtnich, 1980), mentioning managed grassland, fodder
plants, horticultural fruits and cereals, while (Baldock et al., 2000) mentions semi-intensive and intensive (maize, horticulture, glasshouses) for 1999 questionnaire returns. The harvested area of FAOSTAT database (FAO, 2005d) for vegetable was taken to be \(100 \%\) irrigated, as the fruit and berry orchard irrigated area of 960 ha from EUROSTAT seems very low, such as the 0 ha of maize. A very conservative estimate of \(1 \%\) of the cereal harvested area listed by FAOSTAT was assumed to be irrigated, with managed grassland having the biggest share of nearly \(100,000 \mathrm{ha}\), an estimation supported by (Achtnich, 1980) and the large harvested areas of forage clover, rye grass and other forage products of FAOSTAT. Irrigated harvested area was estimated with a cropping intensity of 1, also for vegetables which nearly reach the FAOSTAT harvested area, assuming winter-cold conditions.

National data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

Irrigated crops are winter and summer crops. Winter wheat is grown from November to June, barley from December to April, and rye and rye for fodder from November to May. Potatoes, sugar beets, and vegetables are grown from April to October. All the other summer crops including maize and fodder maize are grown from May to October. Oats and triticale are grown from November to June. Fruit orchards are assumed to be frost irrigated and like managed grassland are assumed to be cultivated throughout the year and both irrigated under dry conditions.

\section*{Estonia}

\section*{Irrigated area:}

Area equipped for irrigation in 2005 was 1,363 ha (Tonismae, 2006). Latest available data on irrigated crop area is in the FAO AQUASTAT country report (FAO, 2005a) mentioning mainly grassland and vegetables. The 3,680 ha actually irrigated in 1995 declined later on, in line with only 600 ha actually irrigated in 1999 (Baldock et al., 2000). These 600 ha are distributed mostly to vegetables ( 250 ha ) and grassland (200 ha), assuming a change in irrigation use from the latter to potatoes, fodder plants, and fruit and berry orchards ( 50 ha each). Irrigated harvested area was estimated with a cropping intensity of 1 , for vegetables an intensity of roughly 1 assuming only short continental summers, a resulting vegetables area only \(10 \%\) of the harvested area from the FAOSTAT database (FAO, 2005d) was used. This is in line with the assumption of only partly irrigated outdoor vegetables due to lack of finance for irrigation infrastructure.

Only national data on irrigated areas are available.

\section*{Cropping seasons:}

The same crop calendars are assumed in Estonia, Finland, Latvia, and Lithuania.
Irrigated crops are mainly vegetables, also potatoes and sugar beets from May to October. Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer.

\section*{Finland}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 103,800 ha and actually irrigated) is for 2003. The actually irrigated area ( \(20,000 \mathrm{ha}\) ) and the crop list beyond those included in EUROSTAT crops was taken from (Baldock et al., 2000) that mentions semi-intensive and mainly intensive horticulture (potatoes, beets, vegetables) for 1999 questionnaire returns. The harvested area of FAOSTAT database (FAO, 2005d) was assumed to stem from one cropping season only. For vegetable, the 9,000 ha harvested area for the year 2000 were assumed to be \(100 \%\) irrigated, roughly \(15 \%\) irrigated area conservative estimation for both potatoes and sugar beets ( 5,000 ha each) replacing the probably erroneous zero values of EUROSTAT for the dry summer of 2003. The rest of the area, \(1,000 \mathrm{ha}\), was assumed to be irrigated managed grassland that has the same share in the harvested area as barley, each ca. \(500,000 \mathrm{ha}\), The conservatively estimated actually irrigated area of 20,000 ha corresponds to the lower value of the 1-3 percent of arable land irrigated in dry summers cited in (Baldock et al., 2000).

Sub-national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

The same crop calendars are assumed in Estonia, Finland, Latvia, and Lithuania.
Irrigated crops are mainly vegetables, also potatoes and sugar beets from May to October. Managed grassland is grown throughout the year and irrigated against water deficiency in summer.

\section*{France}

\section*{Irrigated area:}

The area equipped for irrigation for mainland France is \(2,906,081\) ha, based on the maximum of 1997, 2000 and 2003 of the EIDER database (SCEES, 2006), whereas EUROSTAT mentions slightly lower \(2,842,180\) ha. For the actually irrigated area, data from the agricultural census (SCEES, 2006) was taken ( \(1,575,626\) ha, consistent with the value of EUROSTAT). Crop list from (Baldock et al., 2000) support the EUROSTAT crop list when detailed percentages per crop of 1999 were corrected for probable rounding errors and applied to the actually irrigated area of 2000. Nevertheless, the crop list from AGRESTE was used, as it differentiates more classes than EUROSTAT and both data sets have mutually consistent values. AGRESTE gives details for vegetables, for fodder crops and meadows. Annual fodder crops were assumed to be sorghum and not rye. The area for the fodder crop maize from AGRESTE is nearly the same as the mean 19982004 harvested area for fodder maize cited in the FAOSTAT database (FAO, 2005d). Olive trees, pulses and following (De Réparaz, 1993) the arable crops colza/rapeseed and rice were introduced. Rice harvested area (year 2000) was set to be \(100 \%\) irrigated cultivation area, and subtracted from the value of "other cereals". The rest was distributed to barley and sorghum with relative share of ca. \(85 \%\) and \(15 \%\). Areas of "protéagineux" (legumes in high protein content) was attributed to pulses. From the rest area of 46,287 ha, the bigger share was attributed to rapeseed ( 40,000 ha, less than \(0.5 \%\) of harvested area) and roughly 6,300 ha to olive trees (ca. \(40 \%\) of harvested area. Vegetables are assumed to have a cultivation intensity of 2 in order to yield roughly 265,000 ha, less than the harvested area from FAOSTAT ( \(480,000 \mathrm{ha}\) ), assuming that also rainfed cultivation of vegetables exist. Irrigated harvested area was estimated with a cropping intensity of 1 , besides the mentioned value of 2 for vegetables.

Sub-national data on irrigated areas are available for canton level for the crop lists of AGRESTE (SCEES, 2006) and for region level for the crop list of EUROSTAT.

\section*{Cropping seasons:}

Irrigation calendar is assumed to be the same for Andorra and for France.
Irrigated crops are only summer crops grown between May and September, e.g. sunflower, soya, pulses, rapeseed. Rice is grown from May to September. Maize, maize for fodder, potatoes and sugar beets are grown from April until October. Vegetables are grown from March until November on the same area in two cropping seasons with increasing area in the second season (March - June and July - November). Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer, like grapes and olives in summer. Managed grassland classes of AGRESTE temporary and permanent are assumed to be permanently grown throughout the year and to be irrigated at any time during the year when water stress, most often in summer.

\section*{Germany}

\section*{Irrigated area:}

The area equipped for irrigation based on sub-national statistics is 496,871 ha of the Global Map of Irrigation Areas version 4 (Siebert et al., 2007), mainly based on data from the 2001 inquiry of the national technical association (Fachverband Feldberegnung - Federal Sprinkler Irrigation Association, 2001). For the actually irrigated area the mean value of the surveys of 1998 and 2002 (Statistisches Bundesamt - Federal Statistical Office, 1998) \& (Statistisches Bundesamt - Federal Statistical Office, 2004) was used, differentiating between arable cultures, horticulture and permanent crops. The figure for arable crops irrigated area (187,277 ha) was distributed to known irrigated cultures maize, potatoes and sugar beets. For maize and potatoes the values were proportional to assumed irrigation ratios \(5 \%\) and \(25 \%\) of the respective mean harvested areas 1998-2002 given in the FAOSTAT database (FAO, 2005d). The rest was attributed to sugar beets, roughly \(20 \%\) of the harvested area. The figure for horticulture ( \(40,854 \mathrm{ha}\) ) was similarly distributed to 300 ha of medical plants and spices cited by (Pfleger, 2005), the rest attributed to vegetables without detailed specification. From the figures for permanent crops 220 ha of irrigated hops from (Pfleger, 2005) were withdrawn to yield as rest the irrigated areas of fruit and berry orchards. Irrigated harvested area was estimated with a cropping intensity of 1 , only for vegetables with an intensity of 2 , assuming also non-irrigated vegetable cropping areas.

Sub-national data on irrigated areas are available for the mentioned groups of crops (arable, horticulture, permanent) on Länder level by (Statistisches Bundesamt - Federal Statistical Office, 1998) \& (Statistisches Bundesamt - Federal Statistical Office, 2004).

\section*{Cropping seasons:}

Irrigated crops are mainly summer crops. Maize is grown from May to October, potatoes and sugar beets are grown from April to October. All the other crops are grown from May to October, besides vegetables that have two cropping seasons with the same area (April-June and July-October). Grapes, fruit orchards (frost irrigated) and managed grassland are assumed to be cultivated throughout the year and irrigated under dry conditions.

\section*{Greece}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 1,544,530 ha and actually irrigated ca. \(1,16 \mathrm{Mha}\) ) for 2000 was used. The crop list beyond those included in EUROSTAT crops was taken mainly from (Baldock et al., 2000) mentioning semi-intensive (maize); intensive (cotton, beets, horticulture, vines) and extensive tree crops for 1999, along with traditionally trees and horticulture. Fodder crops were distributed to the harvested area of fodder maize ( \(6,940 \mathrm{ha}\) ) and the rest to annual summer fodder plants ( \(66,300 \mathrm{ha}\) ). The mean 1998-2002 harvested area maize for fodder, also that for additional crops rice, cotton, olive trees, pulses, and vegetables was taken from the FAOSTAT database (FAO, 2005d). Rice, cotton and vegetables were assumed to be \(100 \%\) irrigated, olive tree cultures and pulses to have roughly \(20 \%\) irrigated areas of harvested area. Finally, wheat other than durum wheat filled the rest of the actually irrigated areas, about \(50 \%\) of the area for durum wheat, only \(5 \%\) of irrigated area of maize. Actually irrigated area was estimated with a cropping intensity of 1 , besides for vegetables an intensity of 2 .

Sub-national data on irrigated areas are available for the EUROSTAT crop list. Some information of regional distribution of crops at prefecture level is given in on pages 41-43 in (Bazzani et al., 2001).

\section*{Cropping seasons:}

Crop calendars are assumed to be the similar for Italy and Greece
In winter, only winter wheat is irrigated from November to May. Irrigated crops are mainly summer crops, also cotton, grown between April and September. Rice is grown from May to September. Potatoes and sugar beets are grown from April until October. Vegetables are grown from March until November on the same area in two cropping seasons (March - June and July - November). Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer, like grapes and olives in summer.

\section*{Hungary}

\section*{Irrigated area:}

The area equipped for irrigation is 292,147 ha for 2002-2003 as used in the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). On actually irrigated area, very different values are cited. EUROSTAT data (EUROSTAT, 2005) is 67,100 ha for 2000 and 148,690 ha for 2003, while the National Water Authority gives values within the period 1998-2003 from 33,800 ha in 1999 up to 115,200 ha in 2003, and two different figures for 2004 ( 87,500 ha and 102,856 ha) (Ligetvári et al., 2006). Therefore, the mean of the EUROSTAT values for 2000 and 2003 and of the National Water Authority 1998-2003 was used (103,764 ha). As the crop list of EUROSTAT is not exhaustive, other sources were used to fill the areas with unspecified crops. The crop list of (Achtnich, 1980) mentions, besides some 28,000 ha in 1972 for paddy rice, cereals, roots \& tubers, alfalfa, fodder crops, vegetables, fruit orchards, also especially important maize. The cultivated areas for 2000-2002 of (Bundesministerium für Verbraucherschutz, 2003) were used as control especially for vegetables. For rice, the FAOSTAT database (FAO, 2005d) mean harvested area was assumed to be \(100 \%\) irrigated. Pulses were assumed to be \(1 / 3\) irrigated, rapeseed roughly \(10 \%\), tobacco \(100 \%\), annual spices roughly \(10 \%\), managed grassland \(100 \%\) ( \(9,000 \mathrm{ha}\) ). Finally, areas for
barley (ca. \(5 \%\) irrigated), wheat other than durum wheat (ca. \(1 \%\) irrigated) were estimated. Harvested irrigated area was estimated with a cropping intensity of 1.

\section*{Cropping seasons:}

Irrigated crops are mainly summer crops. Winter cropping seasons are present for wheat and barley. The cropping season of winter wheat lasts from November to June, that of barley from December to May. All the other annual crops are grown from May to October, with the following exceptions: potatoes and sugar beets start in April. Rice is grown from May to September. Vegetables have one cropping season from April to October. Grapes, fruit orchards (frost irrigated) and managed grassland are assumed to be cultivated throughout the year, with possible irrigation during dry seasons.

\section*{Iceland}

No irrigation due to climatic conditions unsuitable for outdoor horticulture agriculture was assumed. No figures from the FAOSTAT database (FAO, 2005d) are available.

\section*{Ireland}

\section*{Irrigated area:}

Actually irrigated and equipped areas for 1999 were both set equal to the total actually irrigated area of 1,100 ha cited in (Baldock et al., 2000), with early potatoes ( 500 ha ), vegetables ( 500 ha ) and strawberries (100 ha). Irrigated harvested area was estimated with a cropping intensity of 1, also for vegetables.

Only national data on irrigated areas are available.

\section*{Cropping seasons:}

Irrigated crops are mainly summer crops grown between April and September. Strawberries are classified as perennial, e.g. sunflower, soya, pulses, rapeseed. Rice is grown from May to September. Maize, maize for fodder, potatoes and sugar beets are grown from April until October. Vegetables are grown from March until November on the same area in two cropping seasons with increasing area in the second season (March - June and July - November). Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer, like grapes and olives in summer. Managed grassland is grown throughout the year, but only irrigated in summer.

\section*{Italy}

\section*{Irrigated area:}

Area equipped for irrigation on a community level is \(3,892,202\) ha according to the Italian agricultural census of 2000 (ISTAT, 2002). Actually irrigated area is \(2,471,379\) ha according to the same source. The EUROSTAT data (EUROSTAT, 2005) on irrigated area for 2000 are slightly different, mentioning area equipped for irrigation of \(4,084,290\) ha from sub-national data and actually irrigated area of \(2,453,460\) ha. From the ISTAT data, data on durum wheat, soft wheat, maize for grain, sugar beet, sunflower, soybeans, vegetables (tomatoes and others), grapes/vine,
fruits, potatoes, citrus fruits, fodder/grazing and other cultures can be derived. The EUROSTAT crop list is non-exhaustive and does not mention vegetables. As (Baldock et al., 2000) mentions olives, vines, fruit trees, field crops, horticulture for southern Italy and cereals, maize, rice for northern Italy, the ISTAT area of "other cultures" was set to comprise maize for fodder (50 \% of 'grazing'), rice, olives, and other cultures. The area of EUROSTAT class "fodder plants" is identical with that for ISTAT class "grazing". Sub-national distributions of ISTAT area shows very high percentages of irrigation of the cultivated areas for north-western region of Italy, especially between roughly \(45 \%\) and \(60 \%\) for provinces Piemonte, Valle d'Aosta, and Lombardia, and northeastern Italy, especially between roughly \(25 \%\) and \(35 \%\) for provinces Trentino-Alto Adige and Veneto. These areas are assumed to be mainly managed grassland. As their sub-total corresponds to roughly \(50 \%\) of the total class area, \(50 \%\) of the "grazing/fodder plants" class area, ca. 139,000 ha was assumed to be managed grassland. The other \(50 \%\) were assumed to be maize for fodder, corresponding to roughly \(20 \%\) of the harvested area from the FAOSTAT database (FAO, 2005d)). The rest area was distributed to rice harvested area from FAOSTAT ca. 220,000 ha, assumed to be \(100 \%\) irrigated, next olive trees, of which \(25 \%\) of the harvested area or roughly 297,000 ha was assumed to be from irrigated areas, and finally about 9,000 other annual crops. Besides for vegetables, irrigated harvested area was calculated with a cropping factor of 1. Vegetables with a cropping intensity of 2 double the area of 199,000 ha to 398,000 ha harvested area, which is still less than the 602,000 ha rounded FAOSTAT harvested area of the year 2000.

Sub-national data on irrigated areas are available from ISTAT and from EUROSTAT.

\section*{Cropping seasons:}

Crop calendars are assumed to be the similar for Italy and Greece.
In winter, only winter wheat is grown from November to May. Besides this exception, irrigated crops are mainly summer crops (cotton is marginal or not existent), grown between April and September. Rice is grown from May to September. Potatoes and sugar beets are grown from April until October. Vegetables are grown from March until November on the same area in two cropping seasons (March - June and July - November). Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer, like grapes and olives in summer.

\section*{Latvia}

\section*{Irrigated area:}

The EUROSTAT database (EUROSTAT, 2005) mentions equipped area of 590, 1,150 and 790 ha for 2000, 2003, and 2005 respectively. The area equipped for irrigation, 1,150 ha, for 2003 was taken as the reference. and actually irrigated 0 ha are for 2003. This is far less than the 20,000 ha irrigated area that is cited in the 1997 version of the FAO AQUASTAT Country Profile (FAO, 2005a) and that is assumed to be the equipped area at that time. 569 ha are cited to have sprinkler irrigation in 2001(Latvia, 2002). The AQUASTAT country profile lists as major irrigated crops potatoes, vegetables and sugar beets. This was assumed to be still reasonable, as for Lithuania potatoes and vegetables are cited elsewhere. It was assumed that the zero actual irrigation area according to EUROSTAT was rather a lack in data than a real estimate (like for neighbouring Estonia and Lithuania). Hence, the mean of the equipped areas 2000-2005 was set to be actually irrigated ( 833 ha ) for the mentioned crops with \(30 \%, 40 \%\) and \(30 \%\) shares, respectively. Irrigated harvested area was calculated with a cropping intensity of 1 also for vegetables, a vegetables area only \(5 \%\) of the harvested area cited in the FAOSTAT database (FAO, 2005d) resulted. This is in
line with the assumption of only partly irrigated outdoor vegetables due to lack of finance for irrigation infrastructure.

Only national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

The same crop calendars are assumed in Estonia, Finland, Latvia, and Lithuania.
Irrigated crops are mainly vegetables, also potatoes and sugar beets from May to October.

\section*{Liechtenstein}

No irrigation assumed due to climatic conditions. The FAOSTAT database (FAO, 2005d) only mentions grapes (120 ha, 1998-2002).

\section*{Lithuania}

\section*{Irrigated area:}

The area equipped for irrigation given by ICID for 1998 is 8,112 ha (Lithuanian National Committee of ICID, 2005), and for 20054,416 ha(Ministry of Agriculture, 2005). The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 740 ha and actually irrigated 0 ha) are for 2003. This is, similar to Latvia, far less than the 9,427 ha irrigated area and assumed to be equipped area that is cited in the 1997 version of the FAO AQUASTAT Country Profile (FAO, 2005a) which lists for the year 1990 the irrigated pastures and meadows (ca. \(77 \%\) ), as crops fodder (beets), barley, vegetables, wheat and fruit gardens. According to (Kucera and Genovese, 2004), today the main irrigated crops are potatoes and vegetables. It was assumed that the 230 ha cited by EUROSTAT to be actually irrigated was rather a small figure by lack of data than a real estimate. Hence, the fully equipped area was set to be actually irrigated ( \(4,416.3 \mathrm{ha}\) ) covered \(60 \%\) by potatoes and \(40 \%\) by vegetables. Harvested irrigated area for both crops was estimated with a cropping intensity of 1 , for vegetables also, assuming only short continental summers. This results in a vegetables area far below the harvested area from the FAOSTAT database (FAO, 2005d). This is in line with the assumption of only partly irrigated outdoor vegetables due to lack of finance for irrigation infrastructure.

Only national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

The same crop calendars are assumed in Estonia, Finland, Latvia, and Lithuania.
Irrigated crops are mainly vegetables in summer (May - October). Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer.

\section*{Luxembourg}

\section*{Irrigated area:}

As EUROSTAT (EUROSTAT, 2005) mentions no irrigation, other sources of information were taken. (Baldock et al., 2000) lists very little irrigation for small-scale vegetable production. The area of horticulture according to (Ministère de l'agriculture et du développement rural - Service d'économie rurale, 2005) was assumed to be roughly \(75 \%\) equipped for irrigation. The value from the maximum horticulture area for the years 2000-2003 was taken as the area equipped for irrigation ( 27 ha ). The \(75 \%\) value for \(2000(16 \mathrm{ha})\) was assumed to be the currently actually irrigated area and was attributed \(100 \%\) to vegetables. The harvested area of 24 ha was set in accordance to the FAOSTAT data in the reference year 2000 ( 23 ha for 2000; 20 ha for 2003) and a assuming a practiced cropping intensity of 1.5 for vegetables, with 8 ha in the first season and 16 ha in the second. However, it is expected that potentially parts of the much larger fruit harvested area ( \(2,000-3,000 \mathrm{ha}\) ) is irrigated at least in case of frost in spring. As definite

Only national data on irrigated areas are available as given in (Baldock et al., 2000).

\section*{Cropping seasons:}

Irrigated crops are vegetables in summer, grown in two seasons with smaller area from April to June and higher area from July to October..

\section*{Macedonia}

\section*{Irrigated area:}

Current area equipped for irrigation is 127,800 ha (Vukelic et al., 2006). The actually irrigated area 42,500 ha was calculated by using the values of the same source, 30,000 ha for a wet year and 80,000 ha for a dry year, with a \(25 \%\) probability of a dry year. This is much less than the 126,617 ha specified by as currently used irrigated land of (MAKCID, 2005), identical with those given in (Public Water Management Enterprise "Water Management of Macedonia", 2006). The latter values are assumed to be values representing current active equipped areas. The 42,500 ha is distributed for the period 1998-2002 using a selection of major crops according to the list cited in (Vukelic et al., 2006) and the harvested area from the FAOSTAT database (FAO, 2005d). Harvested area of rice ( 3,167 ha mean for 1998-2002) was assumed to be \(100 \%\) irrigated and the remainder area distributed by estimated relative percentages based on harvested areas for the highincome crops vegetables (30 \%), grapes ( \(15 \%\) ), fruit orchards ( \(15 \%\) ), potatoes ( \(10 \%\) ), maize ( \(10 \%\) ), meadows (managed grassland, \(10 \%\) ), sunflower ( \(5 \%\) ), and tobacco ( \(5 \%\) ) that are cited besides rice as crops in the FAOSTAT database (FAO, 2005d). Irrigated harvested area was estimated with a cropping intensity of 1, also for vegetables. The resulting harvested areas are, besides for rice, far less below those given in the FAOSTAT database (FAO, 2005d).

Sub-national data on irrigated areas are available from (Vukelic et al., 2006) and (Public Water Management Enterprise "Water Management of Macedonia", 2006).

\section*{Cropping seasons:}

Irrigation calendar is assumed to be similar in Macedonia, Serbia, Montenegro, and Kosovo.
Irrigated crops are summer crops. Rice, sunflower and tobacco are grown from May to October, maize from April to September. Potatoes and vegetables are grown from April to October. Fruit
orchards are assumed to be frost-irrigated and, like managed grassland, irrigated against water deficiency in summer.

\section*{Malta}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 2,300 ha and actually irrigated \(2,130 \mathrm{ha}\) ) are for 2003. They are in accordance with the 1997 version of the FAO AQUASTAT Country Profile (FAO, 2005a) which lists completely used agricultural area. Crops cited for supplementary reservoir-based irrigation are spring potatoes and vegetables, both also cited in (Achtnich, 1980). Full or partial control-irrigation exists for melons, tomatoes, potatoes, pumpkins, marrow (called squash in the United States) and cauliflower. Therefore, the rest of the actually irrigated area not comprised in the EUROSTAT list of crop (potatoes, fruit and berry orchards, citrus and vines) is fully attributed to vegetables ( \(1,090 \mathrm{ha}\) ), and a harvested area of roughly 2,500 ha assumed, in line with a cropping intensity of 2.5 cited in the AQUASTAT Country Profile. Assuming the up to the same area of non-irrigated vegetable cultures this value fits into the framework of roughly 5,000 ha harvested area for vegetables from the FAOSTAT database (FAO, 2005d). Besides vegetables, all crops have a cropping intensity of 1.

Only national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

Irrigated crops are summer crops. Potatoes are grown from March to November. Vegetables are grown on the same areas in three separate cropping seasons (February - May, June - August, September - November) the first two seasons with 1,090 ha and the last season with a reduced area of only 320 ha, according to the cropping intensity between 2 and 2.5 . Fruit orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Citrus and grapes are grown throughout the year, with irrigation against water deficiency in summer.

\section*{Moldova}

\section*{Irrigated area:}

Area equipped for irrigation which is currently used for Moldova is 307,000 ha cited by the World Bank (World Bank, 2003c), while the newer value for 2002 of value of 280,800 ha is assumed to be more correct (Department of Statistics and Sociology, 2005). Data in the FAO AQUASTAT country profile (FAO, 2005a) and report (FAO, 1997b) on irrigated crops is for 1986 and 1994. The 312,000 ha equipped for irrigation (1994) and the 300,000 ha actually irrigated (1986) correspond excellently to the newer information available at the national statistical institute (Department of Statistics and Sociology, 2005), listing 302,100 ha irrigated land for the year 2000, but not to the lesser value of 230,000 ha cited there for 2003. This latter figure was assumed to be the representative actually irrigated area for the current situation 1998-2002.

The distribution of these areas to the classes in the AQUASTAT report and to crops and subgroups of own nomenclature was done the following way: First, the areas of permanent crops and annual arable crops for 2003 were derived from the total irrigated land area according to the mean relationship for these irrigated land uses for the years 2002-2004, both given in (Department of Statistics and Sociology, 2005). Secondly, the irrigated area with permanent tree crops was
distributed to fruit trees and vines according to the listed crops in (World Bank, 1995) using relative percentages of harvested area from the FAOSTAT database (FAO, 2005d) for the year 2000. Third, the annual crops irrigated area was distributed to the crop groups and crops listed in the AQUASTAT report the according to the relative shares of harvested area (2000) within the groups:
- Fodder crops were distributed to three FAOSTAT-equivalent groups: maize for forage (74 \(\%\) ), mixed grasses ( \(1 \%\) ), and vegetables and roots for fodder ( \(25 \%\) ).
- The cereals were distributed to winter wheat \(40 \%\), barley \(12 \%\), maize \(47 \%\), buckwheat 1 \%.
- Vegetables and potatoes were distributed to \(52 \%\) potatoes and \(48 \%\) vegetables. The AQUASTAT report information on shares of cultivated area that should be irrigated of potatoes ( \(18 \%\) ) and vegetables ( \(70 \%\) ) did not correspond to the given harvested areas especially for vegetables (much higher cropping intensity). For vegetables, a cropping intensity of 2 was assumed.
- As industrial crops sugar beet ( \(90 \%\) ) and sunflower ( \(10 \%\) ) was added, although the harvested area of the latter is much larger than that of the former one, roughly \(20 \%\) and 80 \(\%\). But it was assumed that sugar beets had a much bigger market value and thus were much more likely irrigated than sunflower.
The assumed irrigated harvested areas were calculated with a cropping intensity of 1, for vegetables 2. Besides for vegetables, the FAOSTAT harvested areas are by far not reached.

Only national data on irrigated areas and crops is available from the mentioned sources, with some hints of climate sub-regions in the AQUASTAT report.

\section*{Cropping seasons:}

Irrigated crops are mainly summer crops. In winter, only winter wheat (November - June) and barley (December - April) are grown. In summer, maize, maize for forage, buckwheat, sunflower, and other annual crops assumed to be pulses and are grown from May to October. Potatoes and sugar beets are grown from April to October. Vegetables are grown on the same areas in two separate cropping seasons (April - June, July - October). Fruit orchards are assumed to be frostirrigated and irrigated against water deficiency in summer, similarly also grapes.

\section*{Monaco}

No irrigation assumed in this city-state.

\section*{Montenegro:}

\section*{Irrigated area:}

Current area equipped for irrigation, 2,115 ha, for the year 2004 is cited in the national statistics (Republic of Montenegro Statistical Office, 2006). It is taken to be representative at least for the season 2000-2005. Actually irrigated area ( \(2,115 \mathrm{ha}\) ) for 2004 for arable fields and gardens, orchards, vineyards and meadows (assumed to be managed grassland) were taken from (Serbia and Montenegro Statistical Office, 2005), in order to be compatible with the data for Kosovo for the same season. The crop area for arable fields and gardens (only 9 ha ) were repartitioned using estimated relative percentages for the high-income crops vegetables (ca. \(40 \%\) ), potatoes (ca. \(50 \%\) ) that are cited in (Serbia and Montenegro Statistical Office, 2005). Irrigated harvested area was estimated with a cropping intensity of 1 , also for vegetables, as single cropping is the norm
according to (World Bank, 2005). The resulting harvested areas for the total of Serbia and Montenegro are far less below those given in the FAOSTAT database (FAO, 2005d).

\section*{Cropping seasons:}

Irrigation calendar is assumed to be similar in Macedonia, Serbia, Montenegro, and Kosovo.
Vegetables are cultivated during a relatively long cropping season from March to October. The cropping season for maize starts in April and ends in September. The cropping season of sugar beets and potatoes starts in April, that for tobacco starts in May and both end in October. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes / vines are grown throughout the year. Meadows are assumed to be managed grassland grown / cultivated throughout the year and possibly actually irrigated in the summer.

\section*{Netherlands}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 498,330 ha) is somewhat higher than the reference value of 476,315 ha on municipal level as drawn from (Kroon, 2006). The area actually irrigated representative for the season around \(2000(146,333 \mathrm{ha}\) ) was calculated as mean of dry and wet years cited in the study of (Hoogeveen et al., 2003) for the Droogtestudie Nederland. The area is much higher than the 62,190 ha for the dry year 2003 cited by EUROSTAT and is assumed to be more realistic given the national expertise in its compilation. (Hoogeveen et al., 2003) cites shares for the reference year 1997 for grassland ( \(65 \%\), ca. \(95,000 \mathrm{ha}\) ), maize ( \(7 \%\) ), potatoes ( \(13 \%\) ), vegetables ( \(5 \%\) ), and other crops ( \(10 \%\) ). The absolute areas were calculated by applying these percentages to the current actually irrigated reference area. For "other crops", the relative shares of sugar beet, fodder, and fruit and berry orchards were used to distribute the area to these crops. is roughly \(10 \%\) that correspond to the absolute areas as given by EUROSTAT only for potatoes. The crop lists for 3 geographical regions cited for 1999 in (Baldock et al., 2000) confirm this picture: grass and arable land, some vegetables in the west and north, arable land, horticulture, grass in the east, centre and south, with additionally intensive glasshouse and horticulture all over the country. (Baldock et al., 2000) also mentions grassland as a very important crop. Irrigated harvested area was calculated with a cropping intensity of 1 , for vegetables a cropping intensity of 2 was assumed.

Sub-national data on irrigated areas are available as relative shares for the 5 groups cited in (Hoogeveen et al., 2003) and as areas for the EUROSTAT crop list.

\section*{Cropping seasons:}

Irrigated crops are summer crops. Maize and fodder plants are grown from May to October. Potatoes and sugar beets are grown from April to October. Vegetables are grown on the same areas in two separate cropping seasons (March - June, July - October). Fruit and berry orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Managed grassland is assumed to be potentially irrigated throughout the year.

\section*{Norway}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on area equipped for irrigation (134,396 ha) is for 2000. The actually irrigated area ( \(25,000 \mathrm{ha}\) ) was taken from (Achtnich, 1980) who mentions mainly vegetables and fodder. (Arnoldussen, 2006) mentiones berries, vegetables, cereals, potatoes and grassland, in line with the rounded harvested areas for the year 2000 from the FAOSTAT database (FAO, 2005d) for potatoes ( \(15,000 \mathrm{ha}\) ), vegetables ( \(5,200 \mathrm{ha}\) ), and fruit and berry orchards (together \(4,800 \mathrm{ha}\) ) fit exactly the area specified by (Achtnich, 1980). Assumptions of smaller than harvested areas were made for barley ( \(4,000 \mathrm{ha}\) ) and oats ( \(2,000 \mathrm{ha}\) ) and potatoes ( \(5,000 \mathrm{ha}\) ). The rest of the area was attributed to managed grassland (ca. 3,800 ha) Irrigated harvested area was calculated with a cropping intensity of 1 , also for vegetables.

Sub-national data on areas equipped for irrigation are available from (EUROSTAT, 2005), and partially from (Arnoldussen, 2006).

\section*{Cropping seasons:}

Irrigated crops are summer crops. Barley, oats, potatoes and vegetables are grown from May to October. Fruit and berry orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grassland is assumed to be potentially irrigated throughout the year.

\section*{Poland}

\section*{Irrigated area:}

Maximum of the areas reported as irrigable for the years 2003 and 2005 per province summed up to 134,050 ha area equipped for irrigation, as the . The EUROSTAT data (EUROSTAT, 2005) mention 98,430 ha and (Achtnich, 1980) mentions much bigger areas of irrigated managed grassland than of agricultural land. Similarly (POCID, 2005) mentions 418,000 ha grassland and 62,000 ha arable land, respectively. Actually irrigated area for 2003 according to EUROSTAT is 46,910 ha, while a national ICID contribution lists 83,292 ha (Labedzki et al., 2006). National statistics mention the same value for 2003 and 99,089 ha for 2000 (GUS, 2004). The figure of 83,892 ha is considered to be the most reliable, and was distributed to a selection of the list of irrigation demand of crops in Poland cited in (Labedzki et al., 2006) with the following estimated relative shares: winter wheat ( \(5 \%\) ), maize ( \(5 \%\) ), rye ( \(5 \%\) ), potatoes ( \(15 \%\) ), sugar beet ( \(15 \%\) ), vegetables ( \(20 \%\) ), fruit and berry orchards ( \(20 \%\) ), maize for forage and silage ( \(5 \%\) ), alfalfa ( 10 \(\%\) ), grass and permanent grassland ( \(10 \%\), assumed managed grassland). Irrigated harvested area was calculated with a cropping intensity of 1 , also for vegetables.

Sub-national data on irrigated areas (equipped and actually used) for administrative units for 2003 are available from EUROSTAT (EUROSTAT, 2005) and equipped area for provinces for 2000, 2002 and 2003 by (GUS, 2004).

\section*{Cropping seasons:}

The crop calendar was derived from national information in (Labedzki et al., 2006). Winter wheat and rye are grown from November (assumed) to July, the rest of the irrigated crops being mainly summer crops. Maize, potatoes, sugar beets are grown from April to September. Vegetables are grown from May to September. Fruit and berry orchards are assumed to be frost-irrigated and
irrigated against water deficiency in summer. Alfalfa and managed grassland is assumed to be present throughout the year.

\section*{Portugal}

\section*{Irrigated area:}

The area equipped for irrigation, 792,008 ha, was taken from the agricultural census of 1999 (Instituto Nacional de Estadística - Portugal, 2001). It also presents detailed information on irrigated areas (and number of units) down to the NUTS3 (municipal) level, for 6 regions by region and by municipality and for 11 crop types, including rice that is - like vegetables - not cited in the EUROSTAT list. The actually irrigated area (600,314 ha) for 1999 for continental Portugal on a national level was taken from (Instituto Nacional de Estadística - Portugal, 2001), as the crop list was more complete, even if private gardens were not included. The area of private gardens was assumed to be negligible. The harvested area for sugar cane according to the FAOSTAT database (FAO, 2005d) was assumed to be included in the area of "others".
Harvested areas was calculated with a cropping intensity of 1, for vegetables with an intensity of 2, as the harvested area of vegetables (ca. 84,000 ha for the year 2000) from the FAOSTAT database (FAO, 2005d) suggested such an intensity.

Sub-national data on irrigated areas equipped for irrigation are available from EUROSTAT (EUROSTAT, 2005), although with inconsistent old and new spatial units. The areas actually used for irrigation are listed in the 1999 census (Instituto Nacional de Estadística - Portugal, 2001).

\section*{Cropping seasons:}

The cultivation of summer crops was assumed to start approximately one month earlier than in neighbouring Spain. Main characteristics are winter cropping season of (winter) wheat from November to June. All the other crops (hybrid / regional / silage maize, rice, sugar beet, sunflower) are grown from April to September. Maize for forage in spring cropping season are grouped to other maize seasons, as it is assumed that no specific prediction of whether a field is used for forage or not could be made. Other forage crops are assumed to be grown during this season as well.
The cropping season of potatoes starts in March and end in October. Double cropped tomatoes and horticulture as vegetables have two cropping seasons on the same area (March-June and JulyOctober). All the other crops like fruit orchards, citrus, grapes, olives, and "others" (assumed to be mainly permanent cultures) were taken to be cultivated throughout the year, besides sugar cane whose cultivation is assumed to start in March and end in December as in Spain.

\section*{Romania}

\section*{Irrigated area:}

Area equipped for irrigation is \(2,149,902\) ha according to the Global Map of Irrigation Areas version 4 (Siebert et al., 2007), different from the value of 2,021,911 ha according to (Nicolaescu et al., 2006), not considering the EUROSTAT value of \(1,510,830\) ha (EUROSTAT, 2005). Actually irrigated area for the crop year 2001-2002 (400,518 ha) is provided by the national statistics (National Institute of Statistics - Romania, 2006). This value corresponds to the value given by EUROSTAT for 2003. The crops and their irrigated area are taken likewise from (National Institute of Statistics - Romania, 2006), with the exception of unmentioned rice. For rice the mean harvested area from the FAOSTAT database (FAO, 2005d) for the period 1998-2002 (1,277 ha) was assumed
to be the representative area being \(100 \%\) irrigated. Cotton which is cited like rice, vegetables, maize, soybean, sunflower, wheat, and beets in (Nicolaescu et al., 2006) has only 9 ha harvested area and is therefore neglected. Harvested irrigated area was estimated with a cropping intensity of 1 , for vegetables an intensity of 2 , not reaching the FAOSTAT harvested area.

Sub-national data on irrigated areas (besides rice) are available from (National Institute of Statistics - Romania, 2006) and with less crops from (EUROSTAT, 2005).

\section*{Cropping seasons:}

Main characteristics are winter cropping season of (winter) wheat from November to June. All the other crops (maize, sunflower, soybean, assumed fodder crop maize, other annual crops like flax and hemp) are grown from May to October, besides potatoes and sugar beets (start in April), rice (start in June), and vegetables whose cultivation starts in March and that have two cropping seasons on the same area (March-June and July-October). Grapes, fruit orchards and pastures and meadows are assumed to be cultivated throughout the year, with possible irrigation during dry seasons. Seed cotton was assumed to be irrigated to a negligible and hardly detectable extent between 1998 and 2002, but present for rainfed agriculture.

\section*{Russian Federation}

\section*{Irrigated area:}

Area equipped for irrigation, as derived from "oblast" level data is \(4,899,900\) ha, out of which \(4,002,900\) ha are located in the European part of the country and 897,000 ha in the Asian part of the Russian Federation (Siebert et al., 2007). These figures include 138,000 ha for Chechnya. Other sources list 4,868,000 ha in 1997 (GOSCOMSTAT, 1998) and 4,454,100 ha in 2003 (Kireycheva et al., 2006). For 2003, \(23 \%\) of non-irrigated equipped area is reported by national experts (Kireycheva et al., 2006). This figure is used in order to derive the actually irrigated area of \(3,772,923\) ha. The distribution of areas to crop classes and subgroups was done the following way: The crop areas of (Kireycheva et al., 2006) for 1997 were extended with the areas for industrial crops for 1994 in the AQUASTAT report (FAO, 1997b), and scaled to the 2003 actually irrigated area. For the crop group "cereals and cereal-pulses", the area was distributed using approximately relative shares of harvested area for wheat ( \(40 \%\), ca. \(480,000 \mathrm{ha}\) ), barley ( \(25 \%\), ca. 300,000 ha), rye ( \(10 \%\) ), oats ( \(10 \%\) ), millet ( \(5 \%\) ), buckwheat ( \(5 \%\) ), pulses ( \(5 \%\) ). Fodder crops were assumed to be \(25 \%\) maize for forage and \(75 \%\) managed grassland (ca. 1.5 Mha , FAOSTAT nomenclature "mixed grasses and legumes"). The area for "industrial crops" was distributed to sunflower (10 \%), sugar beets ( \(80 \%\) ), and other annual crops ( \(10 \%\) ). Areas of rice (ca. 165,000 ha), grain maize, vegetables, and potatoes were directly used. Grain maize and fodder maize are summing up to ca. \(615,000 \mathrm{ha}\). For all of these mentioned crops, the irrigated harvested areas were calculated with a cropping intensity of 1 . Nevertheless, the FAOSTAT harvested areas are by far not reached, with the exception of rice.

Only national data on irrigated areas and crops are available from the mentioned sources, with some hints to climate sub-regions.

\section*{Cropping seasons:}

The crop calendar is based on information for the Former Soviet Union given in the United States Department of Agriculture Agricultural Handbook No. 664 (USDA, 1994) and the assisting calendar for the Ukraine in FAO GIEWS (FAO, 2005c).

Main characteristics are a winter cropping season of winter wheat and rye from September to August. Barley and summer cereals are grown from November to May. All the other crops (oats, millet, buckwheat, rice) are cropped from May to August like vegetables and other annual crops. Maize, sunflower, sugar beets, potatoes are grown from May to October. Mixed grasses and legumes (managed grassland) are assumed to grown throughout the year, with possible irrigation during dry seasons.

\section*{San Marino}

\section*{Irrigated area:}

No irrigation was assumed, as in the surroundings no clear irrigation areas could be found.

\section*{Serbia (including Kosovo)}

\section*{Crop area - Serbia including Kosovo:}

Area equipped for irrigation is 163,311 ha, roughly \(45 \%\) in Kosovo and \(55 \%\) in Serbia.
Total actually irrigated area is 60,071 ha. It was distributed to annual crops vegetables, maize, potatoes, sugar beets and tobacco, and to permanent cultures meadows, fruit tree orchards and vineyards.

From different sources for Serbia / Montenegro and Kosovo crop shares were compiled separately:

\section*{Crop area - Serbia:}

Current area equipped for irrigation ( \(86,311 \mathrm{ha}\) ) is assumed to be the sum of the partly and fully operational systems area of the total area of 120,000 ha being cited in (World Bank, 2005). It is taken to be representative at least for the season 2000-2005. Actually irrigated area (28,071 ha) for 2004 for arable fields and gardens, orchards, vineyards and meadows (assumed to be managed grassland) were taken from (Serbia and Montenegro Statistical Office, 2005), from which the areas of Kosovo (SOK, 2005)and Montenegro (Republic of Montenegro Statistical Office, 2006) were subtracted. The crop area for arable fields and gardens were repartitioned using estimated relative percentages for the high-income crops vegetables ( \(35 \%\) ), potatoes ( \(35 \%\) ), maize ( \(15 \%\) ), sugar beets ( \(10 \%\) ), and tobacco ( \(5 \%\) ) that are cited in(Serbia and Montenegro Statistical Office, 2005). Irrigated harvested area was estimated with a cropping intensity of 1, also for vegetables, as single cropping is the norm according to (World Bank, 2005). The resulting harvested areas for the total of Serbia and Montenegro are far less below those given in the FAOSTAT database (FAO, 2005d).

\section*{Crop area - Kosovo:}

Current areas equipped for irrigation ( \(77,000 \mathrm{ha}\) ) for Kosovo were taken from statistical sources (Siebert, 2006). The 160,653 ha as calculated from percentages of irrigated cultivated land area given for the municipal level for 2004 (SOK, 2005), which were weighted with the cadastral area of the cadastral survey for 2003 (KCA, 2003, in order to yield a national level of \(39.8 \%\) irrigated land. This level is similar to the percentage of irrigable land to total utilised agricultural land of neighbour countries Macedonia (ca. \(20 \%\) in 2000) and Greece (ca. \(40 \%\) in 2003). Surprisingly, the resulting national total irrigated area is much higher than the area of 32,000 ha cited by \{SOK, 2005 \#90) in order to yield a national level of \(39.8 \%\) irrigated land. So the absolute area given by the latter is
used as the probably minimum actually irrigated area with respect to the other data yielding the area equipped for irrigation.

The area of 32,000 ha given in (SOK, 2005), i.e. approximately \(50 \%\) of the area equipped for irrigation, is assumed to be actually irrigated. The shares of this area to the crop groups were calculated for vegetables, potatoes, fruit orchards without vines, vine grapes / grapes using the absolute cultivated area of the agricultural survey 2004 (SOK, 2005). As the survey covers roughly a quarter of the country area and does neither represent all private farmers nor the "socially owned enterprises" (e.g. cooperatives) with presumably specialised cropping, the areas of these crops were assumed to be minimum irrigated areas, as possibly in the whole country additional areas exist. For meadows, the number calculated from the national area in the 1980ies multiplied by the national percentage of irrigated cultivated land was used, as the figure for 2004 was extremely large surpassing the arable land area. The rest of the area up to the total was assumed to be irrigated maize. Irrigated harvested area was estimated with a cropping intensity of 1, also for vegetables. No harvested areas can be found in the FAOSTAT database (FAO, 2005d).

Sub-national information of area equipped for irrigation can be derived from percentage of irrigated land cited for municipal level and national percentage of irrigated land for 2003 in (SOK, 2005), and the entity area given in the cadastral survey for 2003 (KCA, 2003).

\section*{Crop calendar - Serbia including Kosovo:}

Irrigation calendar is assumed to be similar in Macedonia, Serbia, Montenegro, and Kosovo.
Vegetables are cultivated during a relatively long cropping season from March to October. The cropping season for maize starts in April and ends in September. The cropping season of sugar beets and potatoes starts in April, that for tobacco starts in May and both end in October. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes / vines are grown throughout the year. Meadows are assumed to be managed grassland grown / cultivated throughout the year and possibly actually irrigated in the summer.

\section*{Slovakia}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on area equipped for irrigation (225,310 ha for 2000) of actually irrigated area ( 104,560 ha for 2003) are the best available sources.(SKNC-ICID, 2005) mentions a higher area equipped for irrigation in 1995, but it is assumed that not all of the area was operational in 2000. The crop area not included in the EUROSTAT crop list was attributed to the harvested area according to the harvested area cited in the FAOSTAT database (FAO, 2005d). For vegetables the full area of 28,000 ha (for 2003), was used assuming a cropping intensity of 1 . The rest was distributed to barley, wheat other than durum wheat, barley and rapeseed assuming that 2 \(\%\) of the harvested area was irrigated. The rest of the area ( \(4,770 \mathrm{ha}\) ) was attributed to managed grassland. The irrigated harvested area was estimated with a cropping intensity of 1 for all crops.

Sub-national data on irrigated areas are available from (EUROSTAT, 2005).

\section*{Cropping seasons:}

Wheat is cultivated during two cropping seasons: Summer durum wheat from May to October and winter wheat from November to June. The summer cropping season for most crops lasts from May (wheat, potatoes, sugar beets, sunflowers, rapeseed) until October. Vegetables are grown during a
short cropping season from June to October. The cropping season for maize starts in April, that for soya in May, and both in September. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes / vines are grown throughout the year. Fodder plants are assumed to be grown like vegetables from May until October. Managed grassland is assumed to be grown / cultivated throughout the year and possibly actually irrigated in the summer.

\section*{Slovenia}

\section*{Irrigated area:}

The area equipped for irrigation ( \(15,643 \mathrm{ha}\) ) was taken from a personal communication of the president of the National Committee of ICID, as the data of (Statistical Office of the Republic of Slovenia, 2006) on area equipped for irrigation ( 6,339 ha for 2003, 5,303 ha for 2004) and on actually irrigated area ( 2,535 ha for 2000) and also from EUROSTAT (EUROSTAT, 2005) \((2,230\) and 1,880 ha, respectively) are obviously underestimating the areas. The actually irrigated area ( \(8,952 \mathrm{ha}\) ) was calculated by applying the ratio of actually irrigated to equipped area for 1999-2002 from the statistical yearbook (Statistical Office of the Republic of Slovenia, 2002) to the equipped area. The distribution of this area to individual crops was made using the shares for 2003 of EUROSTAT for maize, potatoes, fodder plants, fruit and berry orchards (ca. 3,800 ha). Fodder plants were assumed to be maize (total of ca. \(1,100 \mathrm{ha}\) ) according to its dominant share for 2000 cited in (Statistical Office of the Republic of Slovenia, 2006). The rest of about \(50 \%\) of the irrigated area was distributed to crops cited also in (World Bank, 1997): vegetables ( \(40 \%\), ca. 1,400 ha)), pasture ( \(30 \%\), assumed to be managed grassland, ca. 1,000 ha), grapes ( \(25 \%\) ), and wheat ( 5 \(\%)\). The irrigated harvested area was estimated with a cropping intensity of 1 , for vegetables with 2 .

Some sub-national estimation on proportional crop shares for 6 regions is cited in (World Bank, 1997).

\section*{Cropping seasons:}

Wheat is cultivated as winter crop from November to June. Vegetables are grown during two cropping seasons on the same areas from March to June (early vegetables) and from July to October, assuming appropriate climate. The cropping season for maize starts in April and ends in September. For other crops (potatoes, sugar beets) it lasts from May to October. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Grapes like pasture (managed grassland) are permanent cultures.

\section*{Spain}

\section*{Irrigated area:}

The area equipped for irrigation of the national agricultural census 1999 on a municipal level is 3,575,488 ha (Instituto Nacional de Estadística, 2002). The EUROSTAT data (EUROSTAT, 2005) on actually irrigated area \(3,235,510\) ha for 2000 (equipped \(3,828,120 \mathrm{ha}\) ) were used. This annually \(90 \%\) of actually used irrigable areas is the highest percentage within a comparable group of big Mediterranean European Union member countries (respective value for Greece \(75 \%\), Italy \(60 \%\), Portugal \(31 \%\) ). Only half of it is distributed to specific crops in the EUROSTAT database. Therefore, much best possible guess in the estimated distribution of the other half of the area is included. The crop lists of (Baldock et al., 2000) for 3 geographical regions cited for 1999 are taken as reference, in continental regions: maize, beet, cereal, in Mediterranean areas: citrus, horticulture,
rice, in the south: maize, tobacco, rice, horticulture, olives, fruit. All rounded harvested area from the FAOSTAT database (FAO, 2005d) of rice and tobacco were assumed to be irrigated. Based on the assumption of extremely suitable weather for double cropping of high-value vegetable crops, only 200,000 ha were assumed to be irrigated with a cropping intensity of 2 . Sugar cane and cotton harvested areas for 2000 were taken to be fully irrigated, reducing the olive tree areas that were assumed to be roughly by \(1 / 3\) seasonally irrigated, the resulting in roughly 707,000 ha instead of 800,000 ha for total Spain, both consistent with the roughly 271,000 ha that are cited for Andalusia alone (Junta de Andalucía - Consejería de Agricultura y Pesca, 2000). Wheat other than durum wheat was assumed to have the same area as durum wheat, and barley and oats the same relative irrigated percentage as wheat ( \(6 \%\) ), and rapeseed irrigated about \(5 \%\) of the harvested area in 2000 (equalling about \(15 \%\) of the much lower harvested area in 2003). Annual spices of 3,000 ha were assumed to be irrigated, roughly \(50 \%\) of the harvested area of all spices. Finally the rest of the area, roughly 52,000 ha was assumed to be extensively irrigated managed grassland ( \(1 / 5\) of harvested area). Irrigated harvested area was calculated with a cropping intensity of 1 , for vegetables the rounded FAOSTAT harvested area ( \(388,000 \mathrm{ha}\) ) was taken, resulting in an effective cropping intensity of 1.94 .

Sub-national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

Vegetables are grown during two cropping seasons on the same areas from March to June (early vegetables) and from July to October, assuming mainly production on the Mediterranean coast (e.g. Costa del Sol) with appropriate climate. The other crops are assumed to be grown also in other areas of Spain with more continental climate, with a cropping season for maize and cotton starting in April and ending in September, rice from May to September, generally for other crops from May or June (oats, pulses, annual spices) until October. Wheat is grown during two seasons: Durum wheat in the summer half from March to July, and winter wheat from November to June, assumed to be using other areas than durum wheat. Sugar cane is grown from March to December. Fruit tree orchards are assumed to be frost-irrigated and irrigated against water deficiency in summer. Fodder plants are assumed to be grown from May until October. Managed grassland is assumed to be grown throughout the year and possibly actually irrigated in the summer.

\section*{Svalbard and Jan Mayen}

No irrigation due to climatic conditions unsuitable for outdoor horticulture agriculture was assumed.

\section*{Sweden}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on irrigated area (equipped 188,470 ha and actually irrigated \(52,440 \mathrm{ha}\) ) are for 2003. The crop list of EUROSTAT lists zero values for all crops besides potatoes and sugar beets. (Achtnich, 1980) mentions 53,000 ha irrigated area according to FAO in 1977, citing mainly intensive agriculture and horticulture. This list was extended with the crops grass, arable land and some vegetables cited for mainly southern Sweden and for 1999 by (Baldock et al., 2000). In the same source, an irrigation intensity for particularly dry summers is cited for extensive / semi-intensive ( \(20-30 \%\) ) up to intensive ( \(50-60 \%\) ) cultures. It is assumed that the
marketed vegetables are always grown on \(100 \%\) area equipped for irrigation. Thus, for the very dry summer 2003, all harvested area from the FAOSTAT database (FAO, 2005d) of vegetables was taken to be irrigated ( 14,000 ha instead the harvested area of 16,000 ha for 2003 ), then \(30 \%\) and 35 \(\%\) of the harvested area of potatoes and sugar beet, respectively were estimated to be irrigated. A smaller share of managed grassland (ca. \(10 \%\) of harvested area) was assumed to be irrigated. Irrigated harvested area was calculated with an cropping intensity of 1, also for vegetables which were scaled to the FAOSTAT 2000 harvested area, as mentioned before.

Sub-national data on irrigated areas are available for the EUROSTAT crop list.

\section*{Cropping seasons:}

A short cropping season during summer from May to October was assumed. Vegetables start in protected conditions already in April. Managed grassland is grown throughout the year and irrigated against dry conditions in summer.

\section*{Switzerland}

\section*{Irrigated area:}

No EUROSTAT data on irrigated area are available. Area equipped for irrigation ( \(40,000 \mathrm{ha}\) ) was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) that uses the values cited by (Sautier, 2002), more or less in accordance with 30,000 ha in valley bottoms in southerly cantons of FAO for 1977 cited in (Achtnich, 1980). The area actually irrigated for 2000 ( \(12,500 \mathrm{ha}\) ) was estimated with a conservative \(50 \%\) following a maximum area and crop list given for 1992 / 1997 in (BFS, 2001) and distributed according to its maximum share and relative values of (Achtnich, 1980) mentioning managed grassland, horticulture and vines as irrigated crops. Thus, all horticultural area was attributed to be irrigated vegetables ( \(4,000 \mathrm{ha}, \mathrm{ca} .40 \%\) of the harvested area for the year 2000 cited in the FAOSTAT database (FAO, 2005d), fruits as second important crop (ca. \(7 \%\) of harvested area irrigated), followed by grapes / vine ( \(10 \%\) irrigated. Assuming that managed grassland is no longer the most important irrigation, an area of 1,000 ha was attributed in analogy to conditions in Germany and France to EUROSTAT listed maize ( \(5 \%\) of harvested area), potatoes (ca. \(7 \%\) ), sugar beet (ca. \(6 \%\) ), maize for fodder (ca. \(2.5 \%\) ), managed grassland (ca. \(1 \%\) ). Irrigated harvested area was calculated with a cropping intensity of 1 , for vegetables an intensity of 2 was taken, assuming that part of the harvested area for the year 2000 from the FAOSTAT database was non-irrigated in the year 2000 (whereas with a cropping intensity of 2 all vegetables are irrigated in 2003).

Sub-national crop area data is not available from the mentioned sources besides the general hints of (Achtnich, 1980).

\section*{Cropping seasons:}

Most of the irrigated annual crops (maize, potatoes, sugar beets) are cultivated from May to October. Vegetables are cultivated during two cropping seasons with equal lengths from March to June and from July to October). Permanent cultures are fruit orchards (potentially irrigated against frost), vines, and managed grassland assumed to be irrigated during dry conditions in summer.

\section*{Turkey}

\section*{Irrigated area:}

Area equipped for irrigation for \(1994(4,185,910 \mathrm{ha})\) was taken from an FAO AQUASTAT report (FAO, 2005a) \& (FAO, 1997c). The crop calendar for FAO (FAO, 2005b) provided the actually irrigated area \((3,476,000 \mathrm{ha})\) for 1994 with distribution to 16 crops. The vineyards on microirrigation plots by State hydraulic Works (DSI) cited in the AQUASTAT report were neglected, as they no area was specified. The assumed irrigated harvested areas were calculated with a cropping intensity of 1, also for vegetables. Nevertheless, the harvested areas from the FAOSTAT database (FAO, 2005d) are by far not reached.

Only national data are available.

\section*{Cropping seasons:}

The crop calendar from (FAO, 2005b) was used. Main characteristics are cropping seasons during winter for (winter) wheat from November to May, and for barley and fodder crops from December to April. All the other crops are grown from June to October, besides sugar beet that is cultivated from May to October. Permanent citrus, fruit orchards and oil crop cultures are grown from January to December.

\section*{Ukraine}

\section*{Irrigated area:}

As area equipped for irrigation the 2,395,500 ha cited for 1985 for "oblast" level (Anonymous, 1985) are assumed to be still valid for the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). The figure is slightly less than the \(2,605,000\) ha equipped for irrigation in 1994 cited in the FAO AQUASTAT report on the Former Soviet Union (FAO, 1997b). Actually irrigated area in the period 1998-2002 was declining from ca. 1.4 Mha in 1997 and 1.45 Mha in 1998 to ca. 545,000 ha in 2001 and ca. 730,000 ha in 2002 and 2003 (Kovalenko et al., 2006). The mean area of 1998-2002 ( \(1,005,120 \mathrm{ha}\) ) was taken as the reference value, which is much less than the \(2,413,000\) ha actually irrigated area for 1990 cited in the FAO AQUASTAT report (FAO, 1997b). Relative percentages derived from absolute values for 1990 given there were used to calculate areas representative for the period 1998-2002. The results are in line with the dominant crops cereals, fodder crops and "technical crops" cited by (Aljiev et al., 2005). The distribution of area of the classes in the AQUASTAT report to crops and subgroups of own nomenclature was done subtracting mean FAOSTAT harvested area for rice (ca. \(21,190 \mathrm{ha}\) ) from the total actually irrigated area, and then applying the relatives shares for the rest of the crop groups. Within the groups, relative shares based on relative percentages of harvested area from the FAOSTAT database (FAO, 2005d) were used for fodder crops, cereals, and "industrial crops":
- Fodder crops (ca. \(510,000 \mathrm{ha}\), ca. \(52 \%\) of rest of irrigated areas besides rice) were taken to be \(25 \%\) maize and \(75 \%\) mixed grasses \& legumes (assumed to be managed grassland).
- For grain cereals (ca. \(325,000 \mathrm{ha}\), ca. \(33 \%\) of irrigated rest areas), only harvested areas equal or larger than 50,000 ha were considered, thus omitting sorghum that was assumed to need no irrigation at these locations. Slightly adapted percentages were: wheat \(45 \%\), barley \(30 \%\), maize \(15 \%\), rye \(5 \%\), oats \(5 \%\). Furthermore, paddy rice (ca. \(21,000 \mathrm{ha}\) ) was assumed to be \(100 \%\) irrigated.
- Vegetables and potatoes (ca. \(89,000 \mathrm{ha}, 9 \%\) of irrigated rest areas) were distributed to the same share as given in the explicit data for the Russian Federation: 25 \% potatoes and 75 \% vegetables.
- The area of "technical/industrial crops" (ca. 59,000 ha, \(6 \%\) of irrigated rest area) were distributed to the listed crops sunflower ( \(50 \%\) ), sugar beets ( \(40 \%\) ), and additionally to "Other annual crops" (10 \%).
For all of these mentioned crops, the assumed irrigated harvested areas were calculated with a cropping intensity of 1 .

Only national data on irrigated areas and crops are available from the mentioned sources.

\section*{Cropping seasons:}

The crop calendar of the Russian Federation was used. It is based on information for the Former Soviet Union as given in (USDA, 1994) and the assisting calendar for the Ukraine in FAO GIEWS (FAO, 2005c). Main characteristics are cropping seasons during winter for winter wheat and rye from September to August. Spring barley and maize are grown from May to October like sunflower, sugar beets, and potatoes. Other cereal crops (oats, millet, buckwheat, rice) are cultivated from May to August like vegetables and other annual crops. Mixed grasses and legumes (managed grassland) are assumed to grown throughout the year, with possible irrigation during dry parts of the year.

\section*{United Kingdom}

\section*{Irrigated area:}

The EUROSTAT data (EUROSTAT, 2005) on equipped irrigated area ( 228,950 ha from subnational data) are for 2003. Data of actually irrigated area of EUROSTAT (227,400 ha) for the dry year 2003 seems to overestimate the actually irrigated area, as only in Northern Ireland the actually irrigated area is cited to be less than the equipped area. As Wales and Northern Ireland contribute only \(0.6 \%\) and \(0.5 \%\) to the irrigation area according to EUROSTAT, it was decided to use the mean of between the values of EUROSTAT and of (Weatherhead and Danert, 2002) for England for 2001 ( \(147,270 \mathrm{ha}\) ), resulting in 187,205 ha actually irrigated area. EUROSTAT does not give hints on crops, which can be found as relative percentages for 8 sub-national regions in a study of the Cranfield University (Morris et al., 2004): early potatoes (5 \%), maincrop potatoes (47 \%), sugar beet ( \(7 \%\) ), orchard fruit, small fruit, vegetables ( \(27 \%\) ), grass, cereals, and others. Data of (Bazzani et al., 2001) confirm the domination of potatoes in irrigation. The percentages given by (Morris et al., 2004) for England and Wales were assumed to be valid also for Scotland (0 ha actually irrigated in 2003) and Northern Ireland ( 1,110 ha actually irrigated) and applied to the mean actually irrigated area. Cereal area was distributed to barley ( \(33 \%\) ) and wheat ( \(67 \%\) ) and neglecting rye, following the \(1: 2\) relationship in harvested area from the FAOSTAT database (FAO, 2005d). Irrigated harvested area was calculated with a cropping intensity of 1.

Sub-national data on irrigated areas and crops for regions are available from (Morris et al., 2004) and regional sums for old and new statistical regional units from EUROSTAT.

\section*{Cropping seasons:}

Winter cereals (winter) wheat and (winter) barley are cultivated from November to June. Early potatoes and main crop potatoes are grown like vegetables between March and October. All the other crops are grown from May to October. Permanent cultures are grass (assumed managed grassland) and fruit orchards (trees and small fruits) that are grown from January to December.

\section*{OCEANIA}

\section*{Australia}

\section*{Irrigated area:}

The area equipped for irrigation was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). For the 8 states or national territories of Australia the total per state was scaled to the individual monthly maximum actually irrigated area when this area was larger than the original equipped area. They final values sum up to \(2,316,106\) ha for Australia as a whole, as compared to the initial value of roughly 2.06 Mha (Tab. C 16). The irrigated harvested areas for crop groups were taken from for the year 2000 of the national agricultural census for the year 2000 (ABS, 2002) and (ABS, 2001). These sources give a distribution of the areas the level of the states (including Australian Capital Territory) for the following entities:

Tab. C 19: Spatial entities of Australia (states), and their area equipped for irrigation (Unit ha)
\begin{tabular}{clr}
\hline No. & Entity name (state) & Area equipped for irrigation [ha] \\
\hline 1 & Australia_Australian Capital Territory & 75 \\
2 & Australia_New South Wales & 907,050 \\
3 & Australia_Northern Territories & 6,001 \\
4 & Australia_Queensland & 535,571 \\
5 & Australia_South Australia & 157,029 \\
6 & Australia_Tasmania & 61,202 \\
7 & Australia_Victoria & 611,146 \\
8 & Australia_Western Australia & 38,032 \\
\hline
\end{tabular}

The crop list included the following classes: pasture, cereals, rice, other cereals, total cereals, vegetables for human consumption, fruit (including nuts), grapes, sugar cane for crushing, cotton, all other crops. As a first step, the rounded values were scaled to the cited national total value \((2,384,300 \mathrm{ha})\). It was decided to introduce subdivisions of the classes using crop information such as harvested area or number of trees from (ABS, 2002) in order to get more detailed class information with the following procedure:
- The pasture area for 1999 is subdivided on a national scale: annual pasture roughly \(54 \%\) and perennial pasture roughly \(46 \%\). Nevertheless, the area was set to be managed grassland used throughout the year, with the assumption that the equipment was there anyway and would be used at any time within a given year, according to specific meteorological conditions.
- For cereals, only New South Wales was set to have irrigated rice, as the reported total harvested area is only slightly higher than the irrigated rice area. It was assumed that the rest was rainfed rice, e.g. in Queensland. The area of "other cereals" was distributed to crop classes that were cited in the agricultural census using several assumptions: First of all it was assumed that barley was cultivated as winter barley on a rainfed basis only, also possibly cultivated rye as well. The other crop classes "grain sorghum" (assumed to include sorghum for forage/silage/hay), maize, oats, triticale, wheat were filled using assumptions on relative abundance per state, calculated as percentage of harvested area. Maize was assumed to be \(100 \%\) irrigated besides in the state of Queensland ( \(50 \%\) ). Wheat is the crop with the highest rainfed and irrigated harvested area and is assumed to fill the rest of the irrigated "other cereals" area, with the largest irrigated area of an individual class after managed grassland and rice (present in New South Wales).
- The area of potatoes was subtracted from the irrigated "vegetables for human consumption" area using the state-level percentage of potatoes of the total vegetable area as given in (ABS, 2002), as potatoes are contained in this class of the agricultural census.
- For the "other crops" it was assumed that they include peanuts (only present in Queensland, \(50 \%\) irrigated), tobacco ( \(100 \%\) irrigated), all citrus harvested area (mean harvested area for time period 1998-2002 from the FAOSTAT database (FAO, 2005d)) and a rest of unspecified other crops annual. The citrus area national total was distributed to the states via the relative abundance of the number of trees. In order to establish consistency with the tabulated, with the exception that negligible area ( 8 ha ) of the Northern Territories was added to the number of Western Australia (802 ha), assuming that these trees were located in similar climate.
Finally, the rest of the actually irrigated area was determined for each state via subtracting the currently allocated area from the scaled state irrigated area. In the case of New South Wales and Tasmania, these areas have substantial values of ca. 22,000 and 12,000 ha, respectively.

The area for pasture (ca. \(925,000 \mathrm{ha}\) ) is about half of the total irrigated harvested area, as expected from information of (Achtnich, 1980). It is followed by cotton (ca. 430,000 ha), sugar cane (ca. 210,000 ha), rice (ca. 130,000 ha), grapes, fruits, wheat, vegetables (ca. 70,000 ha without potatoes).

\section*{Cropping seasons:}

The crop calendar for irrigated crops for South Africa of FAO (FAO, 2005b) was used as a starting point and showed agreement with the seasons of given by (USDA, 1994) for most of Australia for winter wheat, winter barley (assumed to be not irrigated), and for eastern Australia (Queensland and northern New South Wales) for cotton, sorghum and sugarcane. For cotton, also data of (UNCTAD, 2006) were checked. The resulting crop calendar for irrigated crops was subdivided into the regions as defined by the aforementioned states. Nevertheless, it was assumed that the irrigation seasons were more or less the same for all of the states, as some crops (e.g. sorghum, cotton) are only present in a specific state. Thus, implicitly the calendar is valid. Winter wheat is grown as winter crop from June to November. Summer crops (maize, rice, sorghum, oats, triticale, peanuts, vegetables, potatoes and tobacco) were assumed to be the rest of the annual irrigated crops, and to be grown from December to April (sorghum until May). Cotton is grown from October to April. As permanent crops managed grassland, sugar cane, citrus, grapes and fruit and nut trees are cultivated. A cropping intensity of 1 is assumed for all crops.

\section*{Fiji}

\section*{Irrigated area:}

The area equipped for irrigation, \(3,000 \mathrm{ha}\), was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). It is roughly confirmed by the agricultural profile of the World Resources Institute (WRI, 2006). The irrigated harvested area was assumed to be \(100 \%\) of the equipped area. It was assumed to be totally used by vegetables according to data found at FAO (Chand, 2006).

\section*{Cropping seasons:}

The crop calendar was established according the information given in (Chand, 2006), citing water deficit for the season of May until October and this being the favourite cropping season for vegetables, with a cropping intensity of 1 .

\section*{Guam}

\section*{Irrigated area:}

The area equipped for irrigation is 312.42 ha according to United States Census (USDA and NASS, 2004 c ), roughly \(60 \%\) of the utilised agricultural land. The actually irrigated area ( 312 ha ), assumed to be the total equipped area, was distributed following the order of market values to cited areas of fruit trees (assumed \(100 \%\) irrigated, 59 ha ), root crops (assumed \(50 \%\) irrigated, 14 ha ), pastures (assumed top be managed grassland and \(50 \%\) irrigated, 23 ha ) and the rest to vegetables ( 213 ha ). The areas given in acres were converted to hectares according to the conversion factor of 0.40468564224 ha per acre.

\section*{Cropping seasons:}

The crop calendar like for the neighbouring Northern Mariana Islands was established like for the Philippines. Vegetables and root crops are grown from October to February. Permanent orchards are cultivated. All crops have a cropping intensity of 1.

\section*{New Zealand}

\section*{Irrigated area:}

The area equipped for irrigation, 577,882 ha, was taken from the Global Map of Irrigation Areas version 4 (Siebert et al., 2007). The irrigated harvested areas for crop groups (in total roughly \(380,000 \mathrm{ha}\) ) were taken from the national agricultural census for the year 2002 (Statistics New Zealand, 2003). The irrigated area for cereals was distributed to crops using mean harvested areas (1998-2002) from the FAOSTAT database (FAO, 2005d) as an indicator of existence and extent of crops. It was assumed that only maize was irrigated, but none of the other cereals (wheat and barley). It was assumed that the area given for vegetables did not include potatoes which were set to be only cultivated as rainfed crop. The area of "cut flowers and flower seed growing" was assumed to be permanently used. The area for pasture (roughly \(300,000 \mathrm{ha}\) ) is by far dominating the irrigated areas ( \(79 \%\) of them). Following are vegetables (roughly \(26,000 \mathrm{ha}\) ), grapes ( \(10,000 \mathrm{ha}\) ) and permanent cultures like fruit trees and berry orchards. Areas of not distinctly specified activities of crops and plant growing, and services to agriculture were assumed to be annual cultures.

\section*{Cropping seasons:}

The crop calendar was assumed to be the same as for Australia. No winter crops are irrigated. Summer crops were assumed to be maize and other annual crops and to be grown from December to April. As permanent crops besides managed grassland, fruit and berry orchards, grapes, citrus, and plant nurseries exist. A cropping intensity of 1 is present for all crops.

\section*{Northern Mariana Islands}

\section*{Irrigated area:}

The area equipped for irrigation according to the Global Map of Irrigation Areas version 4 (Siebert et al., 2007) is 59 ha, whereas the United States Agricultural Census mentions 125 ha for the year 2002 (USDA and NASS, 2004d), roughly \(50 \%\) of the harvested cropland ( 357 ha without pastures, pastures: 495 ha ) utilised agricultural land. The actually irrigated area ( 125 ha ), assumed to be the total equipped area according to the census, was distributed following the order of market values to cited areas of fruit trees (assumed \(50 \%\) irrigated, 59 ha), root crops (assumed \(50 \%\) irrigated, 18 ha )
and the rest to vegetables (118 ha). The areas given in acres were converted to hectares according to the conversion factor of 0.40468564224 ha per acre.

\section*{Cropping seasons:}

The crop calendar like for Guam was established from the one of the Philippines. Vegetables and root crops are grown from October to February. Permanent orchards are cultivated. All crops have a cropping intensity of 1 .

\section*{Annex D: Tabular detailed crop calendars for irrigated crops, by entity}

Annex D contains the detailed monthly crop calendars for irrigated crops, sorted by entity code. The annual harvested area and the growing area for each month of the year per crop class or sub-class and its cropping seasons are given, as absolute values in hectare and also as percentage of area equipped for irrigation. The format follows broadly the FAO crop calendars for irrigated crops. Due to restrictions of the database system the total annual harvested area and the total monthly growing area over all crops are cited as first data line and not at the bottom like in the original.

Reference status of the database is 2007-06-12 for the content and includes the correction of formal errors executed in February 2008.

\section*{Annex E: Global maps of irrigated harvested area}

The Annex E contains global maps of harvested area of irrigated crops. In order to have a recognisable distribution on the chosen scale, only crops with more than 15,000 ha irrigated harvested area globally are shown. Cassava, oil palm, and cocoa are below this threshold and would not be clearly visible on the current scale.

Fig. E 1 Global distribution of harvested area of irrigated wheat, as percentage of grid cell area, for 1998-2002

Fig. E 2 Global distribution of harvested area of irrigated maize, as percentage of grid cell area, for 1998-2002

Fig. E 3 Global distribution of harvested area of irrigated rice, as percentage of grid cell area, for 1998-2002

Fig. E 4 Global distribution of harvested area of irrigated barley, as percentage of grid cell area, for 1998-2002

Fig. E 5 Global distribution of harvested area of irrigated rye, as percentage of grid cell area, for 1998-2002

Fig. E 6 Global distribution of harvested area of irrigated millet, as percentage of grid cell area, for 1998-2002

Fig. E 7 Global distribution of harvested area of irrigated sorghum, as percentage of grid cell area, for 1998-2002

Fig. E 8 Global distribution of harvested area of irrigated soybeans, as percentage of grid cell area, for 1998-2002

Fig. E 9 Global distribution of harvested area of irrigated sunflower, as percentage of grid cell area, for 1998-2002

Fig. E 10 Global distribution of harvested area of irrigated potatoes, as percentage of grid cell area, for 1998-2002

Fig. E 11 Global distribution of harvested area of irrigated sugar cane, as percentage of grid cell area, for 1998-2002

Fig. E 12 Global distribution of harvested area of irrigated sugar beets, as percentage of grid cell area, for 1998-2002

Fig. E 13 Global distribution of harvested area of irrigated rapeseed / canola, as percentage of grid cell area, for 1998-2002

Fig. E 14 Global distribution of harvested area of irrigated groundnuts / peanuts, as percentage of grid cell area, for 1998-2002

Fig. E 15 Global distribution of harvested area of irrigated pulses, as percentage of grid cell area, for 1998-2002

Fig. E 16 Global distribution of harvested area of irrigated citrus, as percentage of grid cell area, for 1998-2002

Fig. E 17 Global distribution of harvested area of irrigated date palms, as percentage of grid cell area, for 1998-2002

Fig. E 18 Global distribution of harvested area of irrigated grapes / vine, as percentage of grid cell area, for 1998-2002

Fig. E 19 Global distribution of harvested area of irrigated cotton, as percentage of grid cell area, for 1998-2002

Fig. E 20 Global distribution of harvested area of irrigated coffee, as percentage of grid cell area, for 1998-2002

Fig. E 21 Global distribution of harvested area of irrigated other perennial crops, as percentage of grid cell area, for 1998-2002

Fig. E 22 Global distribution of harvested area of irrigated managed grassland, as percentage of grid cell area, for 1998-2002

Fig. E 23 Global distribution of harvested area of irrigated other annual crops, as percentage of grid cell area, for 1998-2002```
